

LM51772 48-V 4 Switch Buck-Boost Controller with I²C interface

1 Features

- Input range from 3.5 V to 55 V (absolute maximum. 57 V)
- Output voltage 3.3 V to 48 V
- Dynamical V_O programming via I²C from 3.3 V
 - up to 48 V in 20-mV monotonous steps
 - up to 24 V in 10-mV monotonous steps
- Peak current regulation scheme
- Small voltage transition ripple over all operating modes
- Dynamic output voltage tracking (digital PWM tracking input, analog tracking input)
 - Via I²C interface programming
- Shut down quiescent current 3 μ A
- Operating quiescent current 60 μ A
- DRV pin for external FET control
- Operation mode selection for high efficiency in light load and high load conditions:
 - Power save mode (burst/ μ Sleep)
 - Automatic/programmable conduction mode
- Integrated high voltage supply LDO
- Axillary high voltage LDO/reference
- Integrated full-bridge gate drive
 - 2-A peak current capability
 - Bootstrap over and under-voltage protection
 - Integrated boot-strap diode
- Fixed frequency independent from operating mode (boost, buck-boost, buck)
 - Forced PWM mode selectable
 - Switching frequency from 100 kHz to 2.2 MHz
 - External clock synchronization and clock output
- Spread spectrum operation selectable
- High-side output current sensor
 - Programmable from 1 A to 7 A in 50-mA steps
 - ISET pin selectable
- I²C Interface readout of (device configuration, enhanced monitoring features, programmable thermal warning)
- Create a custom design using the LM51772 with the [WEBENCH® Power Designer](#)

2 Applications

- USB Type-C power delivery ([Docking station](#), [PC-monitor](#), [Desktop PC](#))
- Wireless charging
- [Industrial PC/ Rugged PC](#)
- [Battery backup unit](#)
- [Merchant DC/DC](#)
- [avionics](#) / marine sonar
- [Off-highway vehicle](#)

3 Description

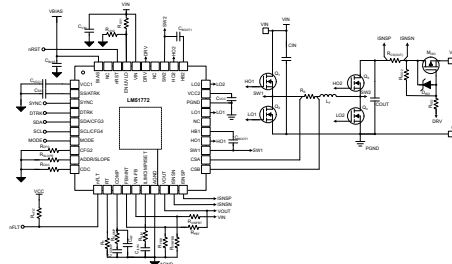

The LM51772 is a four switch Buck-Boost controller. It provides a regulated output voltage if the input voltage is higher, equal or lower than the adjusted output voltage. In power save mode the device supports very high efficiency over the complete operation range of the output. The LM51772 runs at a fixed switching frequency, which can be set via the RT/ SYNC pin. The switching frequency remains the constant during buck, boost and buck-boost operation in forced PWM. The external compensation pin allows very fast transient responds for different applications. [\(Continued\)](#)

4 Description (continued)

The device maintains small mode transition ripple over all operating modes. The output voltage and device configurations can be dynamically programmed via the integrated I²C interface. The integrated and optional high side current sensor features an accurate and output current limitation. The constant current limit of the LM51772 is also configurable through the I2C interface.

ADVANCE INFORMATION

Table 5-1. Pin Functions

PIN		I/O ⁽¹⁾	DESCRIPTION
NAME	NO.		
VCC1	1	O	Internal VCC1 regulator blocking capacitor. If the output is disabled by the logic it can be tied to GND with a resistor or pulled to VCC2. Do not leave the pin floating.
SS/ATRK	2	I/O	Soft-start programming pin. A capacitor between the SS pin and AGND pin programs soft-start time. Analog output voltage tracking pin. The VOUT regulation target can be programmed by connecting the pin to variable voltage reference (for example, through a digital to analog converter). The internal circuit selects the lowest voltage applied to the pin.
SYNC	3	I	Synchronization clock input. The internal oscillator can be synchronized to an external clock during operation. If the output or input current sense amplifier is configured as a current limiter, pulling this pin is low during start-up, device switches the current limit direction to a negative polarity. <i>Do not leave this pin floating.</i> If this function is not used, connect the pin to VCC. The SYNC pin can be configured as internal clock synchronization output signal. The clock signal is phase shifted by 180° to directly operate two devices in a parallel (dual phase) operation.
DTRK	4	I	Digital PWM input pin for the dynamical output voltage tracking. <i>Do not leave this pin floating.</i> If this function is not used, connect the pin to VCC or GND.
SDA/CFG3	5	I/O	I ² C interface serial data line. Connect an external a pull-up resistor If I2C is disabled. this pin is a further configuration pin. Connect a resistor between the CFG3-pin and GND to select the device operation
SCL/CFG4	6	I	I ² C interface serial clock line. Connect an external a pull-up resistor If I2C is disabled. this pin is a further configuration pin. Connect a resistor between the CFG4-pin and GND to select the device operation
MODE	7	I	Digital input to select device operation mode. If the pin is pulled low, power save mode (PSM) is enabled. If the pin is pulled high, the forced PWM or CCM operation is enabled. The configuration can be changed dynamically during operation. <i>Do not leave this pin floating.</i> If this function is not used, connect the pin to VCC or GND.
CFG2	8	I/O	Device configuration pin. Connect a resistor between the CFG2 pin and GND to select the device operation for spread spectrum (DRSS), short circuit protection (hiccup mode), current limit, or current monitor.
ADDR/ SLOPE(CFG1)	9	I	Slope Compensation and Address selection. This pin also disables the I2C interface to use the SCL, SCA as additional slope configuration pins. Connect a resistor between the CFG1 pin and GND to select the device operation
CDC	10		Cable drop compensation output. Connect a resistor between the CFG pin and GND to select the gain for the cable drop compensation. Per default this pin provides a current monitoring signal of the sensed voltage between the ISNSP and ISNSN pins
nFLT/nINT	11	O	Open-drain output pin for fault indication or power good. This pin can be configured as interrupt pin. In case of a STATUS register change the pin toggles low for 256us.
RT	12	I/O	Switching frequency programming pin. An external resistor is connected to the RT pin and AGND to set the switching frequency
COMP	13	O	Output of the error amplifier. An external RC network connected between COMP and AGND compensates the regulator of the output voltage feedback loop.
FB/SEL_intFB	14	I	Feedback pin for output voltage regulation. Connect a resistor divider network from the output of the converter to the FB pin. Connect the FB pin to VCC to operate at a fixed output voltage of 12 V. To select the internal feedback connect the pin to VCC2 before the device start-up
VIN-FB	15		VIN Sens with same divider as FB for VOUT to maintain PCM with external feedback operation.
ILIMCOMP/ISET	16		Compensation pin for current limit loop. Connect an RC filter if the current limit is set by the internal DAC. Sets the current limit threshold for the average current limit. Connect a resistor to GND Connect the ISET pin to VCC to disable the block and reduce the quiescent current

Table 5-1. Pin Functions (continued)

PIN		I/O ⁽¹⁾	DESCRIPTION
NAME	NO.		
AGND	17	G	Analog Ground
VOUT	18	I	VOUT sense input. Connect to the power stage output rail.
ISNSN	19	I	Negative sense input of the output or input current sense amplifier. An optional current sense resistor connected between ISNSN and ISNSP can be located either on the input side or on the output side of the power stage. In case the current monitor is disabled connect ISNSN to ground
ISNSP	20	I	Positive sense input of the output or input current sense amplifier. An optional current sense resistor connected between ISNSN and ISNSP can be placed either on the input side or on the output side of the power stage. In case the current monitor is disabled connect ISNSP to ground
CSB	21	I	Inductor peak current sense negative input. Connect CSB to the negative side of the external current sense resistor using a low-current Kelvin connection.
CSA	22	I	Inductor peak current sensor positive input. Connect CSA to the positive side of the external current sense resistor using a low-current Kelvin connection.
SW1	23	P	Inductor switch node for the buck half-bridge
HO1	24	O	High-side gate driver output for the buck half-bridge
HB1	25	P	Bootstrap supply pin for buck half-bridge. An external capacitor is required between the HB1 pin and the SW1 pin, respectively, to provide bias to the high-side MOSFET gate driver.
NC	26	O	Not Connected
LO1	27	O	Low-side gate driver output for the buck half-bridge
PGND	28	G	Power Ground
VCC2	29	O	Internal linear bias regulator output. Connect a ceramic decoupling capacitor from VCC to PGND. This rail supplies the internal logic and the gate driver.
LO2	30	O	Low-side gate driver output for the boost half-bridge
HB2	31	P	Bootstrap supply pin for boost half-bridge. An external capacitor is required between the HB2 pin and the SW2 pin, respectively, to provide bias to the high-side MOSFET gate driver
HO2	32	O	High-side gate driver output for the boost half-bridge
SW2	33	P	Inductor switch node for the buck half-bridge
NC	34	O	Not Connected
DRV1	35		External FET drive pin. This pin features a high-voltage push pull stage, a open drain output or a charge pump driver stage according to the selected configuration.
VIN	36	I	The input supply and sense input of the device. Connect VIN to the supply voltage of the power stage.
EN/UVLO	37	I	Enable pin. Digital input pin to enable the converter switching. The input features a precise analog comparator to monitor the input voltage and maintains an under voltage lookout by connecting a resistor divider to VIN to the pin.
nRST	38	I	Digital input pin to enable the device internal logic, interface operation and the VCC1 regulator if selected.
NC	39	O	Not Connected
BIAS	40		Optional input to the VCC bias regulator. Powering VCC from an external supply instead of VIN can reduce power loss at high V_{IN} .
GND	PAD	G	Thermal pad

1. I = Input, O = Output, I/O = Input or Output, G = Ground, P = Power.

6 Specifications

Note

- By operating the device with input voltages above 36 V the current limit circuit can get shortly turned off during the SW1 node rising up. This results in a unregulated peak current and oscillations of the peak current loop.
- By operating the device with output voltages above 36 V the device can turn of the high side switch and restart
- By connecting the ILIMCOMP/ISET pin to VVC2 to disable the function, the device operation gets unstable due to internal coupling. To disable the ILIM function the following cases are recommended:
 - disabled the current sensor fully. Pull ILIMCOMP to 4V by dividing VCC2 with 10kΩ and 40kΩ
 - IMON enabled (e.g. for CDC) but ILIM disabled. Pull ILIMCOMP/ISET to GND, do not leave the pin floating

The limitations above are intended to be removed for the final and qualified material.

6.1 Absolute Maximum Ratings

Over the recommended operating junction temperature range of -40°C to 150°C (unless otherwise specified)⁽¹⁾

		MIN	MAX	UNIT
Input	BIAS, VIN to AGND	-0.3	57	V
	ISNSP, ISNSN to AGND	-0.3	57	
	EN/UVLO, nRST	-0.3	57 ⁽⁴⁾ $V_{(VIN)} + 5$ ⁽⁴⁾	
	ATRK/SS, DTRK, RT, SYNC, MODE, SDA, SCL, SLOPE, CFG, IMONCOMP, CDC, to AGND	-0.3	5.8	
	FB to AGND	-0.3	5.8	
	CSA, CSB to AGND(DC)	-5	57	
	SW1, SW2 to AGND(DC)	-5	57	
	HB1 to SW1, CSA, CSB	-0.3	5.8	
	PGND to AGND	-0.3	0.3	
Output	VCC1, VCC2 to AGND	-0.3	5.5	V
	VOUT to AGND	-0.3	57	
	LO1, LO2, to AGND (DC)	-5	$V_{(VCC)} + 0.3$	
	nFLT to AGND	-0.3	5.8	
	HO1, HO2, HB1, HB2 to AGND (DC)	-0.3	63	
	COMP, IMONOUT to AGND ⁽²⁾	-0.3	5.8	
Storage temperature, T _{STG}		-55	150	°C
Operating junction temperature, T _J ⁽³⁾		-40	150	

- Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- This pin has an internal max voltage clamp which can handle up to 1.6mA.
- High junction temperatures degrade operating lifetimes. Operating lifetime is de-rated for junction temperatures greater than 125°C.
- Both of the stated conditions need to be observed

6.2 Handling Ratings

				VALUE	UNIT
V _(ESD)	Electrostatic discharge	Human body model (HBM), per AEC Q100-002 ⁽¹⁾		±2000	V
		Charged device model (CDM), per AEC Q100-011	Corner pins	±750	
			Other pins	±500	

(1) AEC Q100-002 indicates that HBM stressing shall be in accordance with the ANSI/ESDA/JEDEC JS-001 specification.

6.3 Recommended Operating Conditions

Over the recommended operating junction temperature range of –40°C to 150°C (unless otherwise specified)⁽¹⁾

		MIN	NOM	MAX	UNIT
V _(VIN)	Input Voltage Sense	3.3	48	55	V
	Input/Bias start-up voltage	3.5			V
	Minimum voltage for PCM operation	6			V
V _(VOUT)	Output Voltage Sense	3.3	48	55	V
V _(ILIM)	ISNSP; ISNSN	2.8		55	V
R _(ISNS)	Output current limit sense resistor	9.9	10	10.1	mΩ
V _(VCC)	VCC Voltage	3.6		5.3	V
V _(VCC2)	VCC2 Voltage		3.3		V
C _(VCC2)	VCC regulator output capacitance	6			μF
C _(VCC1)	VCC regulator output capacitance	2			μF
V _{FB}	FB Input	0	V _(VCC) +0.3		V
V _{IL}	Logic pin low-level (MODE, DTRK, SYNC, SDA, SCL)			0.4	V
V _{IH}	Logic pin high-level (MODE, DTRK, SYNC, SDA, SCL)	1.3			V
F _{SW}	Typical Switching Frequency	100		2200	kHz
F _{SYNC}	Synchronization switching Frequency range	100		2200	kHz
T _J	Operating Junction Temperature ⁽²⁾	–40		125	°C

(1) Operating Ratings are conditions under the device is intended to be functional. For specifications and test conditions, see Electrical Characteristics.

(2) High junction temperatures degrade operating lifetimes. Operating lifetime is de-rated for junction temperatures greater than 125°C.

6.4 Thermal Information

THERMAL METRIC ⁽¹⁾		LM51772	UNIT
		QFN	
		40 PINS	
R _{qJA}	Junction-to-ambient thermal resistance	33.9	°C/W
R _{qJC(top)}	Junction-to-case (top) thermal resistance	26.6	°C/W
R _{qJB}	Junction-to-board thermal resistance	15.4	°C/W
Y _{JT}	Junction-to-top characterization parameter	0.4	°C/W
Y _{JB}	Junction-to-board characterization parameter	15.4	°C/W
R _{qJC(bot)}	Junction-to-case (bottom) thermal resistance	4.4	°C/W

(1) For more information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application report.

6.5 Electrical Characteristics

Typical values correspond to $T_J = 25^\circ\text{C}$. Minimum and maximum limits apply over $T_J = -40^\circ\text{C}$ to 125°C . Unless otherwise stated, $V_{(\text{BIAS})} = 12\text{ V}$

PARAMETER			MIN	TYP	MAX	UNIT
SUPPLY CURRENT						
	Shutdown current into VIN	$V_{(\text{VIN})} = 48\text{ V}$, $V_{(\text{BIAS})} = 0\text{ V}$ $V_{(\text{EN})} = 0\text{ V}$	$T_J = 25^\circ\text{C}$	3.6		μA
	Shutdown current into BIAS	$V_{(\text{VIN})} = 0\text{ V}$, $V_{(\text{EN})} = 0\text{ V}$	$T_J = 25^\circ\text{C}$	2.8		μA
	Quiescent current into BIAS	$V_{(\text{EN})} = 3.3\text{ V}$, $V_{(\text{FB})} > 1\text{ V}$, uSleep enabled, ILIMCOMP = $V_{(\text{VCC2})}$, EN_VCC1 = 0b0	$T_J = 25^\circ\text{C}$	25		μA
VCC1 REGULATOR						
	VCC1 regulation	$V_I = 12.0\text{ V}$, $I_{(\text{VCC1})} = 1\text{ mA}$		5		V
	VCC1 drop-out voltage	$I_{(\text{VCC1})} = 34\text{ mA}$;	$V_I = 5\text{ V}$	0.6		V
			$V_I = 4.5\text{ V}$	0.6		V
	VCC1 sourcing current limit	VCC1=GND	$V_I = 12\text{ V}$	34		mA
VCC2 REGULATOR						
	VCC2 regulation	$V_{\text{BIAS}} = 12.0\text{ V}$, $I_{(\text{VCC2})} = 20\text{ mA}$		5		V
	VCC2 drop-out voltage	$I_{(\text{VCC2})} = 45\text{ mA}$	$V_I = 4\text{ V}$	130		mV
			$V_I = 3.5\text{ V}$	190		mV
	VCC2 sourcing current limit	$V_{(\text{VCC2})} \geq 3\text{ V}$	$V_I = 6\text{ V}$, $V_{\text{BIAS}} = 12\text{ V}$	260		mA
$V_{T+(\text{VCC2})}$	Positive going threshold	$V_{(\text{VCC2})}$ rising		3.35		V
$V_{T-(\text{VCC2})}$	Negative going threshold	$V_{(\text{VCC2})}$ falling		3.05		V
V_{T+} (Force, BIAS)	Positive going threshold for Forced $V_{(\text{BIAS})}$	FORCE_BIASPIN = 0b1		4.4		V
V_{T+} (VCC2, SUP)	Positive going threshold for LDO switch-over			6.5		V
	VCC2 UVLO rising detection delay time	$V_{(\text{VCC2})}$ rising		100		μs
nRST						
$V_{T+(nRST)}$	Enable positive-going threshold	nRSTrising		1.4		V
$V_{T-(nRST)}$	Enable negative-going threshold	nRST falling		0.35		V
EN/UVLO						
$V_{T+(\text{UVLO})}$	UVLO positive-going threshold	$V_{(\text{EN/UVLO})}$ rising		1.25		V
$V_{T-(\text{UVLO})}$	UVLO negative-going threshold	$V_{(\text{EN/UVLO})}$ falling		1.2		V
$V_{\text{hyst}(\text{UVLO})}$	UVLO threshold hysteresis	$V_{(\text{EN/UVLO})}$ falling		50		mV
I_{UVLO}	UVLO hystereses sinking current	$V_{(\text{EN/UVLO})} < 1.26\text{ V}$		5		μA
$t_{d(\text{UVLO})}$	UVLO detection delay time	$V_{(\text{EN/UVLO})}$ falling;		30		μs
SYNC						
$V_{T+(\text{SYNC})}$	Sync input positive going threshold			1.19		V
$V_{T-(\text{SYNC})}$	Sync input negative going threshold			0.41		V
	Sync activity detection frequency			99		kHz

8 Detailed Description

8.1 Overview

The LM51772 is a four switch Buck-Boost controller. It provides a regulated output voltage if the input voltage is higher, equal or lower as the adjusted output voltage. In power safe mode the device supports a superb efficiency over the full range of the output.

The LM51772 runs at a fixed switching frequency, which can be set via the RT/SYNC pin. The switching frequency remains the same during buck, boost and buck-boost operation. The device maintains small mode transition ripple over all operating modes.

The output voltage and device configurations can be dynamically programmed via the integrated I2C interface. The integrated and optional high side current sensor features an accurate and output current limitation. The constant current limit of the LM51772 is also configurable through the I2C interface.

8.2 Functional Block Diagram

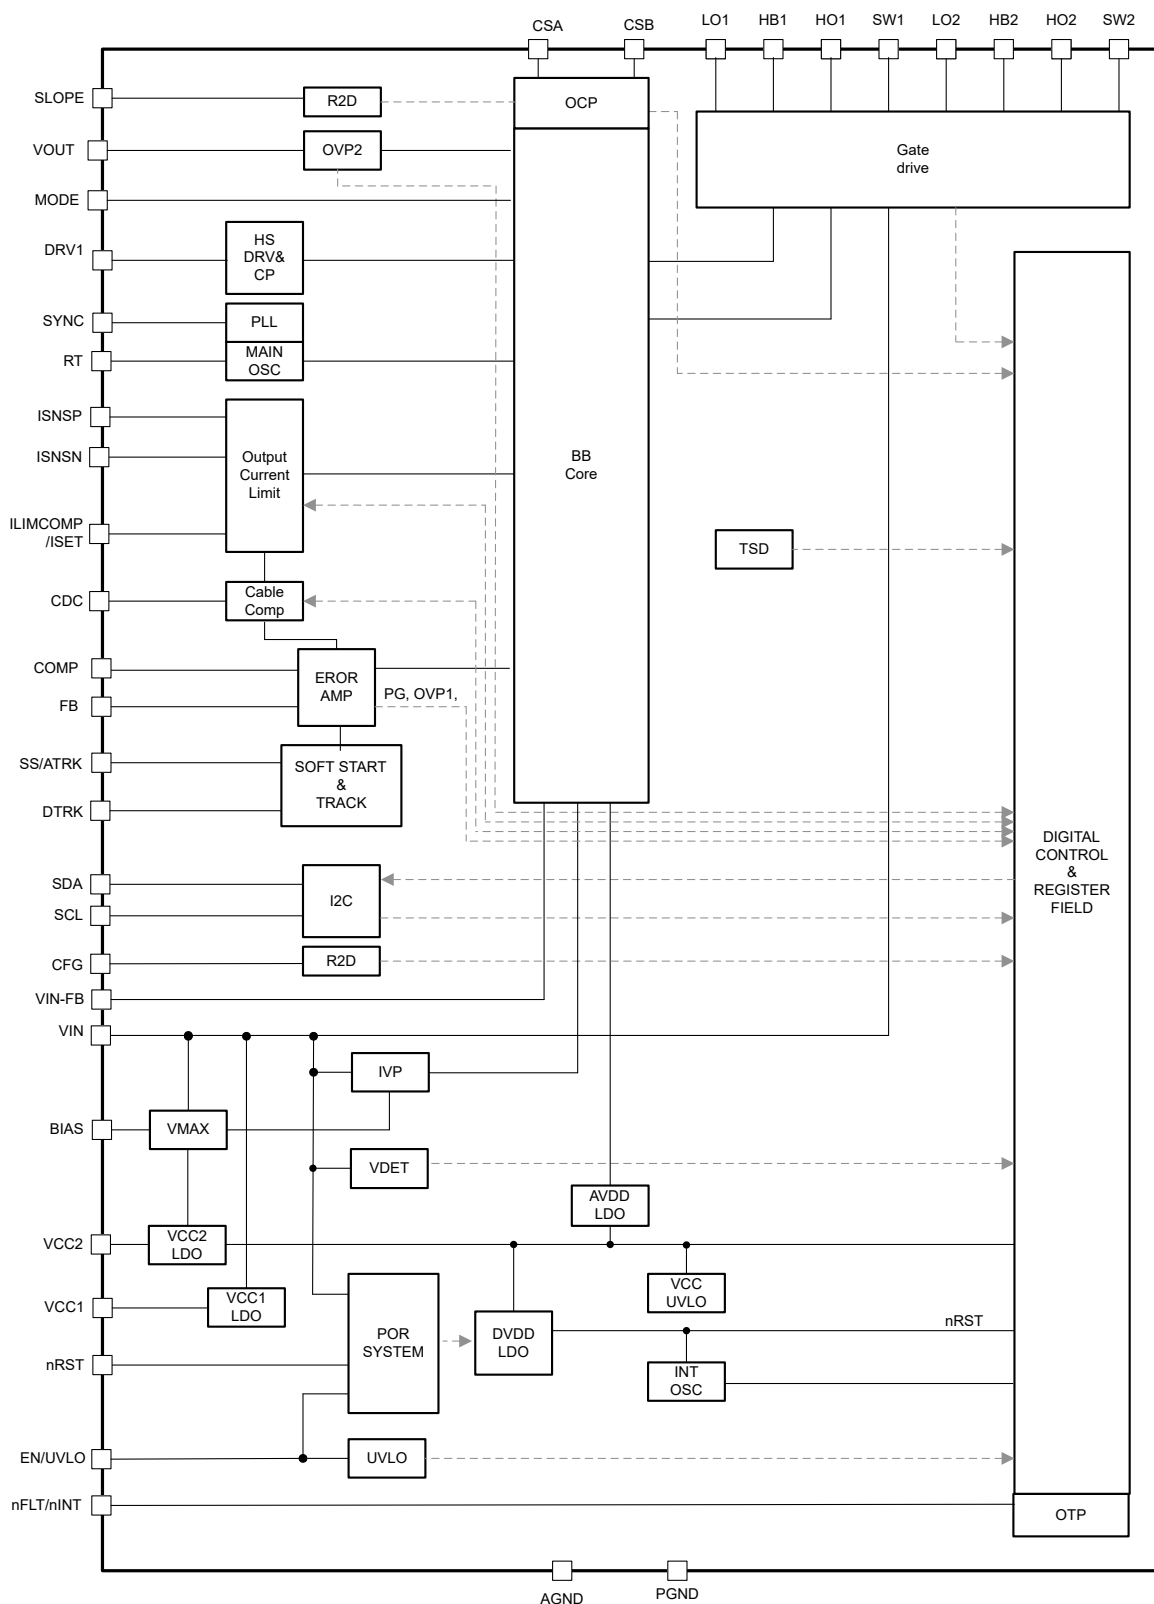

Figure 8-1. LM51772 Functional Block Diagram

ADVANCE INFORMATION

8.3 Feature Description

8.3.1 Buck-Boost Control Scheme

The LM51772 buck-boost control algorithm makes sure there is a seamless transition between the different operation modes, the fixed frequency operation, and the power stage protection features. The internal state machine controls the flowing three active switching states:

State I: Transistor Q1 and Q3 are conducting. Q2 and Q4 are not conducting (boost mode magnetization state).

State II: Transistor Q1 and Q4 are conducting. Q2 and Q3 are not conducting (boost demagnetization or buck magnetization state).

State III: Transistor Q2 and Q4 are conducting. Q1 and Q3 are not conducting (buck demagnetization state).

Switch	State I	State II	State III
Q1	ON	ON	OFF
Q2	OFF	OFF	ON
Q3	ON	OFF	OFF
Q4	OFF	ON	ON

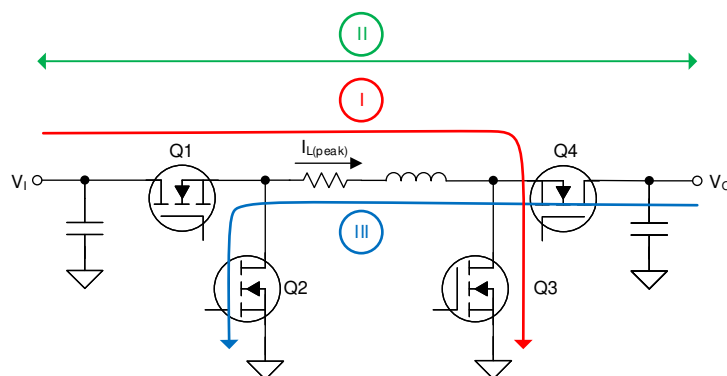

Figure 8-2. Buck-Boost Active Switching States

8.3.1.1 Buck Mode

In buck mode operation, the converter starts a buck magnetization cycle (state II) with the internal clock signal. When the inductor reaches its peak current, the converter proceeds to the buck demagnetization state III. With the next clock signal, the converter changes back to a buck magnetization cycle and starts a new switching cycle with sampling the peak current. As long as the duty cycle does not reach the minimum off time, the current control remains in buck operating mode.

Figure 8-3. Inductor Current in Continuous Current Boost Operation

8.3.1.2 Boost Mode

In boost mode operation, the converter starts a boost magnetization cycle (switching state I) with the internal clock signal. After it samples the inductor current, the device transitions to switching state II, which is the boost demagnetization state. The maximum duty cycle in boost mode is limited by the minimum boost on time and the selected switching frequency.

Figure 8-4. Inductor Current in Continuous Current Boost Operation

8.3.1.3 Buck-Boost Mode

As soon as the on time in buck mode operation exceeds the minimum on time or the off time in boost mode exceeds the minimum off time, the control transits to the buck-boost operation. In the continuous current buck-boost mode, the control adds a boost magnetization (state I) switching cycle before the peak current is reached. Therefore, buck-boost operation mode always consists of all three switching cycles state I, state II, and state III. The peak current detection in this mode happens at the end of switching state I.

Figure 8-5. Inductor Current in Continuous Buck-Boost Operation

8.3.2 Power Save Mode

With the MODE pin low, power save mode is active. In this operating mode, the switching activity is reduced and efficiency is maximized. If the mode pin is high, power save mode is disabled. The converter operates in continuous conduction mode.

In boost or in buck mode, the converter is operating up to the duty cycles with the respective minimum off times or on times. If the timing limits are reached, the output voltage increases. As soon as this happens, the voltage regulation loop detects the increase and turns the device into a TI proprietary sleep mode as the energy consumed by the load is less than what the converter generates during switching. In this mode, both low sides are turned on to ensure the high-side gate voltage supply voltage for HB1 and HB2 are charged. Other internal circuits are partially turned off to reduce the current consumption of the converter to a minimum possible. In case the output voltage reaches the nominal output voltage set point, the switching activity starts again.

In the buck-boost area where larger or smaller duty cycles is necessary, switching pulses are skipped. When necessary, the control initiates switching activities with a minimum time of state I or state III to maintain the inductor current as required by the voltage regulation loop.

Figure 8-6. Timing Diagram for the Power Save Mode

8.3.3 Programmable Conduction Mode PCM

The device also features a power save technique for high current applications. The main drawback of in most of the fixed frequency buck-boost operation are the power losses of the 4 active switches during this mode. The Programmable Conduction Mode (PCM) is forcing the converter PWM logic to stop the switching operation in a programmable input voltage window. This function is available after the soft-start of the converter stage finishes. If the input voltage is inside the PCM window the output voltage approximately equals the input voltage as both high side FETs (Q1, Q4) are connecting the input to the output via the external power stage. Outside the programmed V_I window the selected thresholds are representing the nominal regulation targets of the converter.

The FETs supply are maintained by the integrated charge pump circuit of the device. During the PCM the current limit for the peak current protection is fully operational and the user benefits from a cycle-by-cycle current limit. The SCP hiccup protection can be used to overcome excessive thermal heating during a short like in the normal operation.

The integrated charge pump will operate down to the min. recommended PCM voltage. It is not recommended to program the PCM threshold below this value.

For low output currents and load profiles that have light load conditions the MODE pin can be used to further reduce the power consumption during the PCM is active. If the MODE pin is low the PCM deactivates the internal bias circuits to reduce the power consumption by monitoring the low inductor current.

The two voltage thresholds for this window are customer programmable via the I2C interface or selectable through the corresponding R2D pins.

Figure 8-7. Output Voltage vs. Input Voltage

If you using the I2C interface of the device the upper threshold is set by the VOUT_TARGET1 logical register. The lower threshold is given by the hysteresis referenced to the V_o target and the selected hysteresis value set by the PCM_HYST register field.

If the thresholds are set by the external feedback divider and R2D the upper threshold is the voltage given by the FB-PIN and is equal to the nominal output voltage if the PCM is disabled. The lower threshold is programmed by the PCM_HYST register field and can be enabled/disabled via R2D pin. In case of using the ext. FB and R2D the VIN-FB-pin need to be connected to the input voltage using the same divider ration as the divider placed for V_o and connected to the FB-pin.

The OVP1 and power good thresholds of the protection features are fully functional if PCM is enabled and the input voltage outside the programmed window i.e. the convert regulates active to one of the two thresholds.

ADVANCE INFORMATION

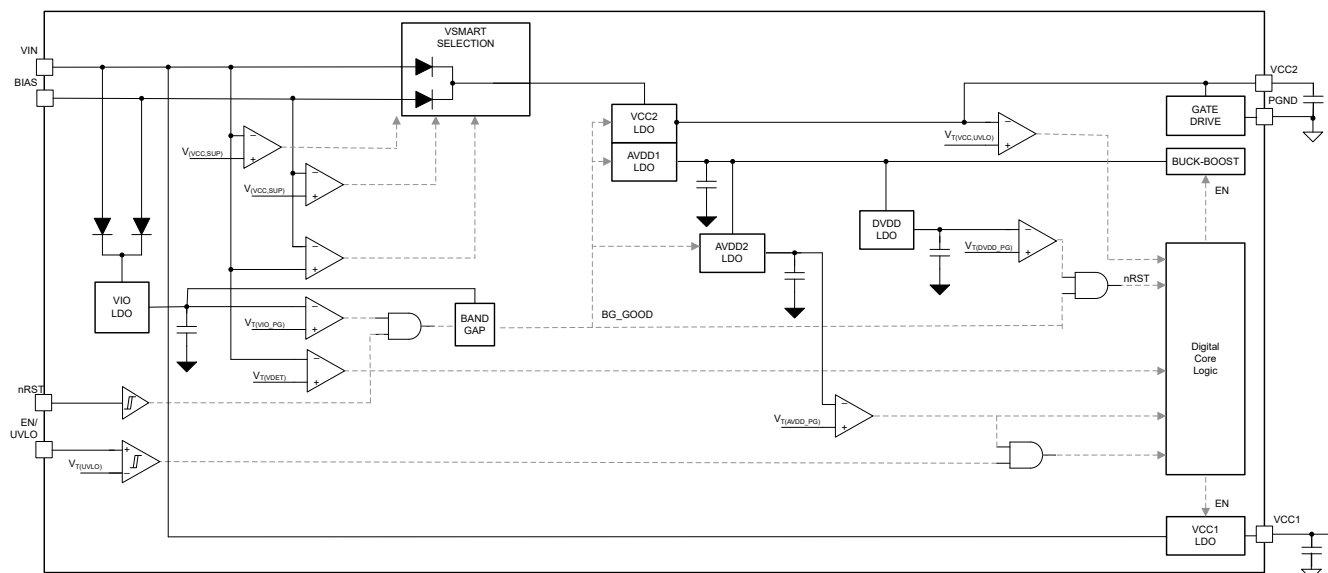

Figure 8-8. Functional Block Diagram Reference System

8.3.4.1 VIO LDO and nRST-PIN

The VIO LDO supplies the IO pin buffers and comparators. Once the voltage on the VIN-pin or BIAS-pin is above the positive going POR threshold $VT+(POR)$ and the nRST-PIN is higher than $VT+(nRST)$ the internal bias is active and the device is in standby mode.

When the nRST - pin is below the standby threshold $V_{T-(nRST)}$, the device is held in a low power shutdown mode to maintain a minimum input quiescent current of the device supply rails.

8.3.5 Supply Voltage Selection – VMAX Switch and Selection Logic

There are two pins to supply the LM51772 internal voltage regulators. Due to the internal supply voltage selection circuit, the device can reduce the power dissipation by ensuring a seamless operation at low input or output voltages as well as in transient operating conditions like an output short. The VMAX switch selects the pin with the lower voltage from the VIN or BIAS pin once the voltage on both is above the switch-over threshold ($V_{T(VCC, SUP)}$). If one pin voltage is lower than the threshold, the other supply pin is selected. And if both pins are lower than the switch-over threshold, the higher voltage of VIN or BIAS is selected as supply. The following are common configurations for the supply pins:

- The VIN pin is connected to the supply voltage. The BIAS pin is connected to VO. During start-up, that is as long as the output voltage is not higher than the supply switch-over threshold, the VIN supplies the internal regulators. Once VO is high enough, the supply current comes from the BIAS pin.
- Both the VIN pin and the BIAS pin are connected together to the input supply voltage. This configuration is often used in applications where the input supply voltage is usually lower or equal than the output voltage. As the BIAS pin is connected to the input voltage, the device has the full current capability of the internal regulators at low input voltages for start-up.
- The VIN is connected to the input supply voltage and the BIAS pin is connected to an auxiliary supply (for example, an existing 12-V DC/DC converter). This configuration is commonly used at high voltage applications on the input and output voltages where the power dissipation over the integrated linear regulators must be further minimized.

Figure 8-9. VMAX Supply Scenario 1

Figure 8-10. VMAX Supply Scenario 2

Figure 8-11. VMAX Supply Scenario 3

The VMAX does not directly select the highest voltage between the two supply pins BIAS and VIN. To achieve a minimum of power losses over the LDO the VMAX logic will decide what voltage is the closest one to the target supply $V_{T(VCC,SUP)}$. The gives an overview for the selection conditions

The selection can be overwritten by NVM setting (e.g. only use the BIAS pin as VMAX supply)

Table 8-1. VMAX selection truth table

$V_{(BIAS)}$	$V_{(VIN)}$	VMAX supply
X	$> V_{T+(VCC,SUP)} \ \&\& \ < V_{(BIAS)}$	VIN-PIN
$> V_{T+(VCC,SUP)} \ \&\& \ < V_{(VIN)}$	X	BIAS-PIN
$< V_{T-(VCC,SUP)}$	X	VIN-PIN
X	$< V_{T-(VCC,SUP)}$	BIAS-PIN
$> V_{T+(VCC,SUP)} \ \&\& \ > V_{(VIN)}$	$> V_{T+(VCC,SUP)}$	VIN-PIN
$> V_{T+(VCC,SUP)}$	$> V_{T+(VCC,SUP)} \ \&\& \ > V_{(BIAS)}$	BIAS-PIN

There is a FORCE_BIAS bit if it is 0b1 it lowers and prioritizes the switchover threshold for the BIAS pin. Intention is to support an external supply of nominal 5V for the VCC2 but still be able to start-up with the VIN supply if the sequencing if the external supply does not meet the start-up timing. The selection of the VCC2 supply follows this behavior:

- If the BIAS voltages is below the $V_{T+(Force,BIAS)}$, then the VIN gets selected.
- If the BIAS voltage is above $V_{T+(Force,BIAS)}$, then the BIAS gets selected regardless of VIN being above the $V_{T+(VCC,SUP)}$

8.3.6 Enable and Undervoltage Lockout

The LM51772 has a dual function enable and undervoltage lockout (UVLO) pin. Furthermore, the device features an internal UVLO function (VDET) which can be programmed through I2C interface. Figure 8-12 shows the UVLO block diagram.

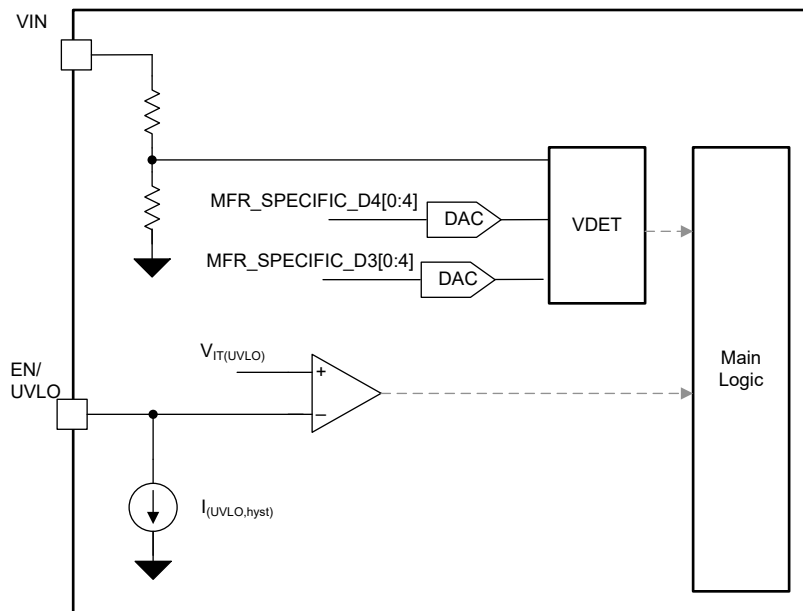

Figure 8-12. Functional Block Diagram UVLO and VDET

8.3.6.1 UVLO

With this function the device can detect an low input voltage condition for the power stage to avoid a brown out condition. The detection threshold as well as the required hysteresis is adjustable with the external voltage divider on the EN/UVLO - pin.

The UVLO features an internal delay time ($t_{d(UVLO)}$) for the shutdown to avoid any undesired converter shutdown due to input noise on the UVLO detection pin. The voltage on the EN/UVLO - pin must below the $V_{T-(UVLO)}$ threshold for the delay time $t_{d(UVLO)}$. Once these conditions are met the device logic will immediately stop the converter operation

If the EN/UVLO-pin voltage is above the $V_{T+(EN)}$ threshold the internal current source for the UVLO hysteresis is active. If the EN/UVLO-pin voltage is above the $V_{T+(UVLO)}$ threshold the internal current source for the UVLO hysteresis is off.

8.3.6.2 VDET Comparator

The VDET features an internal UVLO for the device. The comparator output goes directly to the digital main logic to enable/disable the converter operation.

The rising and falling threshold can be programmed via the VDET_RISE, VDET_FALL register field. The VDET_EN register field enables or disables the function.

For seamless functionality is recommended to change the programmable VDET parameters in the CONV_OFF state.

If the programming for the VDET thresholds changes, make sure to disable the block via the EN_VDET register field first. Change the threshold register(s) and activated the VDET block again by setting EN_VDET to 0b1

8.3.7 Internal VCC Regulator

8.3.7.1 VCC1 Regulator

The LM51772 features a VCC1 regulator which provides an LDO output for auxiliary use in the system. VCC1 gets directly supplied by VIN pin. In most applications the output is used to supply the I2C controller device which sends data to the LM51772. You can find a drawing for this application below.

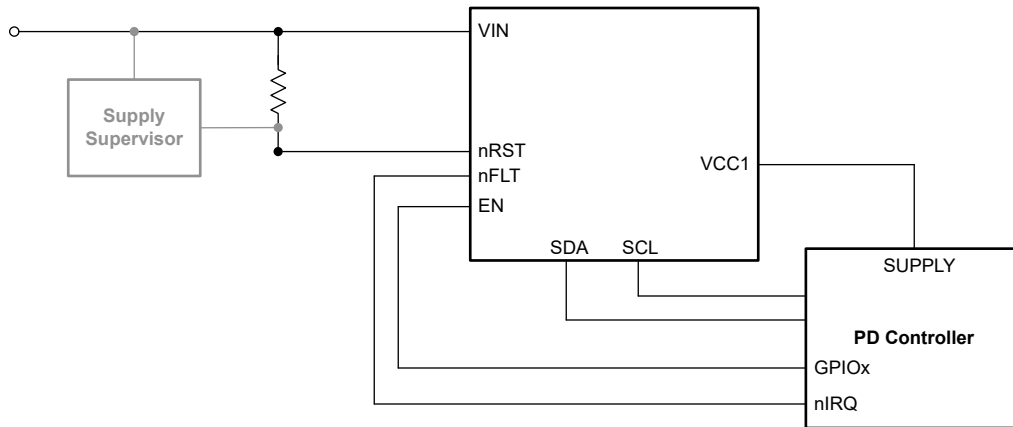

Figure 8-13. Simplified Schematic

To ensure the power sequence of such a system can be met the VCC1 starts-up when the device is entering the standby mode. See a typical power up sequence below.

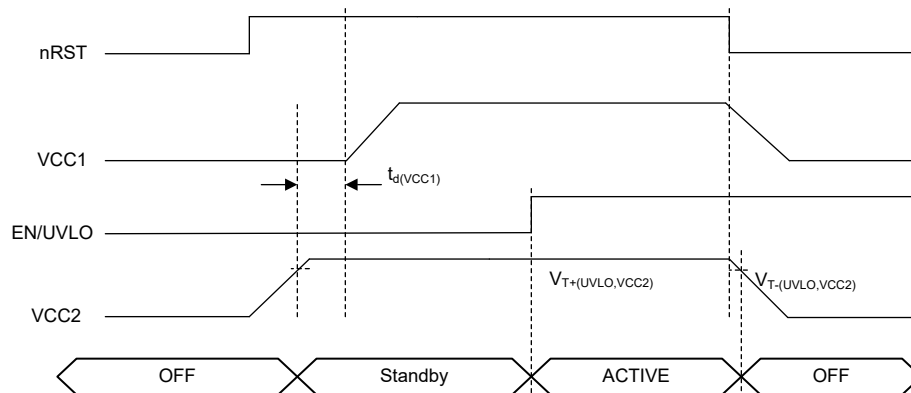

Figure 8-14. Timing Diagram VCC Regulator

The VCC1 regulator provides high DC accuracy at light load condition to support a use as a reference voltage for external circuits e.g. a comparator or operational amplifier.

The VCC1 is enabled/disabled via R2D interface. Therefore the start-up of VCC1 is gated by the R2D readout.

8.3.7.2 VCC2 Regulator

The VCC2 regulator is the supply for the integrated gate driver. The LDO starts to enable and pre-bias once the voltage on the nRST-Pin is higher than its rising threshold. If the EN/UVLO pin is higher than its rising threshold the VCC2 is fully active and provides the target performance specified by the electrical characteristics parameters.

It is not recommended to connect an external load to the VCC2-PIN

8.3.8 Error Amplifier and Control

8.3.8.1 Output Voltage Regulation

The device features an internal error amplifier (EA) to regulate the output voltage. The output voltage gets sensed on the FB-pin. The reference for the EA is supplied via the soft-start and V_O tracking pins. The COMP-pin is the output of the gm-stage and gets connected to the external compensation network.

The voltage over the compensation network is the target for the inner current control loop which sets the inductor peak current demand.

8.3.8.2 Internal Output Voltage Regulation

To maintain fixed voltage and interface programmable voltage the device contains an internal voltage divider. In this case the FB is not applicable for sensing the output voltage for the loop regulation. Instead the VOUT-pin is used to sense the output voltage on the power stage.

The device detects via the FB-pin if it shall operate with an external or internal voltage divider. If the voltage on the FB-pin is higher than $V_{T+(SEL_iFB)}$, before the soft-start is initiated, if the part should operate with a internal or external feedback. The selection of internal and external FB cannot be done dynamically and the pin information gets latched until the next EN or $V_{(POR)}$ power cycle.

The resolution of the programming can be changed with the SEL_DIV20 bit.

If the V_OUT register read back is used the low voltage clamping will be done with whatever SEL_DIV20 value is programmed at this time. If SEL_DIV20 is updated after VOUT_A, the clamping might not be correct anymore. To guarantee correct clamping its recommended to (re-)write VOUT_A after changing SEL_DIV20 bit.

Below an overview of the possible Vo setting according the VOUT_A and SEL_DIV20

SEL_DIV 20 = 0b0:

Parameter	Value
Output voltage min.	3.3V
Output voltage max.	24 V
Output voltage programming step size typ.	10mV

You can use the following equation to calculate the nominal output voltage:

$$V_{(O,NOM)} = [[VOUT_TARGET1_MSB[3:0]][VOUT_TARGET1_LSB[7:0]]] \cdot 10\text{ mV} \quad (1)$$

SEL_DIV 20 = 0b1:

Parameter	Value
Output voltage min.	3.3V
Output voltage max	48 V
Output voltage programming step size typ.	20 mV

Table 8-23

The read-out register value of the 'VOUT_A' control register is clamped for the lower and for the upper limit of the register range.

- The reg. readout value is clamped to the lowest clamp voltage (e.g. 3.3V if SEL_FB_DIV20 = 0b1) if a register value below the value of clamp voltage (e.g. 3.3V) has been written in before.
- The reg. readout value is clamped to the highest clamp voltage (e.g. 48V if SEL_FB_DIV20 = 0b1) if a register value above the highest value of clamp voltage (e.g. 48V) has been written in before.

You can use the following equation to calculate the nominal output voltage:

$$V_{(O,NOM)} = [[VOUT_TARGET1_MSB[3:0]][VOUT_TARGET1_LSB[7:0]]] \cdot 20\text{ mV} \quad (2)$$

ADVANCE INFORMATION

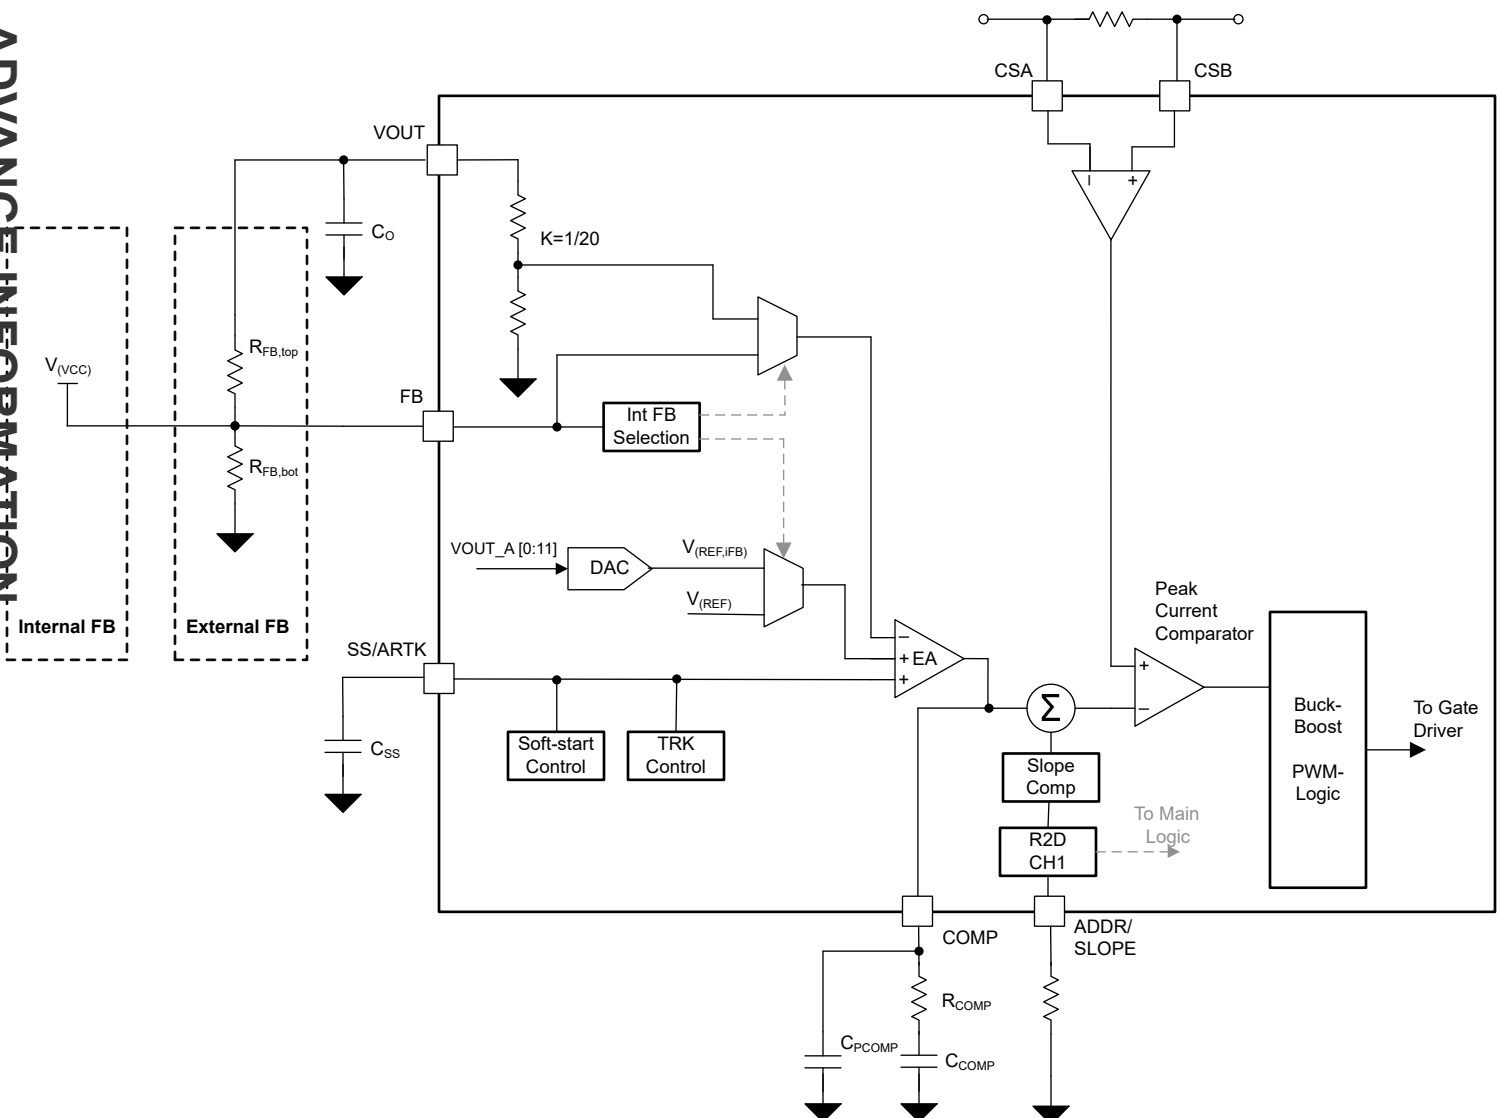

Figure 8-15. EA Functions Block Diagram

8.3.8.3 Dynamic Voltage Scaling

The device features a dynamic voltage scaling. In case the output voltage register gets programmed during the converter is in operation. It shall avoid any excessive current and voltage spike as the control loop bandwidth is

set by external components. If the output voltage target gets programmed in the converter off state the soft-start will ramp to newly programmed target voltage.

Once the VOUT_A field of the register is changed the reference voltage will slowly change-over to the new target value. The rising and falling slew rate shall not exceed the defined $\Delta V_{O(DVS)}$ within the time $t_{d(DVS)}$ the slope time is programmable via NVM setting.

If the converter operates in PSM i.e. the inductor current cannot go to negative values. The device features a passive and a active DVS configuration, selectable via NVM setting. If passive DVS is selected the V_o slope of the system will not follow the defined DVS slew rates as the output capacitor can only be discharged passively. If active DVS is selected the internal output discharge is active during the negative ramp of the DVS. The maximum discharge current is used for the active DVS setting not the register selection of the discharge strength. The output capacitor voltage can follow the reference as long as the capacitor is selected to match the maximum discharge current.

If you use the internal feedback or a fixed voltage version, It is not recommended to apply a DTRK signal or change ATRK during the o change by the DVS function.

8.3.9 Short Circuit - Hiccup Protection

The LM51772 features a short circuit protection or over current protection. This protection uses cycle-by-cycle peak current sensor connected to the CSA and CSB-pin. There are two modes for this protection. In hiccup mode, the controller stops the converter operation after detecting cycle-by-cycle peak current longer as the hiccup mode on-time. The converter logic initiates a discharge of the soft-start capacitor and the output stays off until the hiccup mode off-time elapses. Then the logic will exit the hiccup mode and re-start the output with a normal soft-start sequence were the soft-start capacitor is charged with the internal current source. If the short or overload persist the hiccup timer starts again after the soft-ramp finishes. If hiccup mode protection is not enabled, the device will operate in cycle-by-cycle current limiting as long as the overload condition persists. The peak inductor current limit in steady state is calculated as shown in [Equation 3](#)

$$I_{L(PEAK, ILIMIT)} = \frac{50mV}{R_{CS}} \quad (3)$$

8.3.10 Current Monitor/Limiter

8.3.10.1 Overview

The device features two high voltage current sensors. The first one maintains the peak current sensing between the CSA and CSB pins. The second current sensor inputs are connected to the ISNSP and ISNSN pins. This optional current sensing provides the capability to monitor (CDC-pin) and limit (ILIMCOMP-pin) either the input or the output current of the DC/DC converter.

If the optional current sense amplifier is not used, the customer can connect the ILIMCOMP pin to VCC2 to turn the bias current consumption of this block and all current limiting/monitoring functions off. It is not recommended to do this dynamical during the operation of the device because the configuration gets latched at start-up of the converter. In other words the current monitoring block cannot be disabled dynamically the pin information gets latched until the next EN, EN_CONV or $V_{(POR)}$ power cycle. It is recommended to directly connect the ILIMCOMP to VCC2 or with a pull-up resistor < 50kΩ.

Use the CFG pins or register table to select the following desired operation modes:

1. If the current sense amplifier operates in monitor configuration i.e. IMON_LIMITER_EN is set to 0b0 by I2C interface or R2D selection both pins, CDC and ILIMCOMP, provide a proportional current to the differential sense voltage.
2. The current monitor block limiter operation is activated via MON_LIMITER_EN bit or the corresponding R2D setting for this signal
3. The negative current limit direction is selected by the EN_NEG_CL_LIMIT or through the R2D selection for this signal

4. If ADDR/Slope (CFG1) selects a I2C address (pin to VCC or GND) the main logic activates the I2C interface and the internal DAC as default reference for the current limit threshold. The value for the DAC is set by the ILIM_THRESHOLD register. The internal DAC can be disabled via a register setting through the I2C interface to set the current limit again by an external resistor on ILIMCOMP

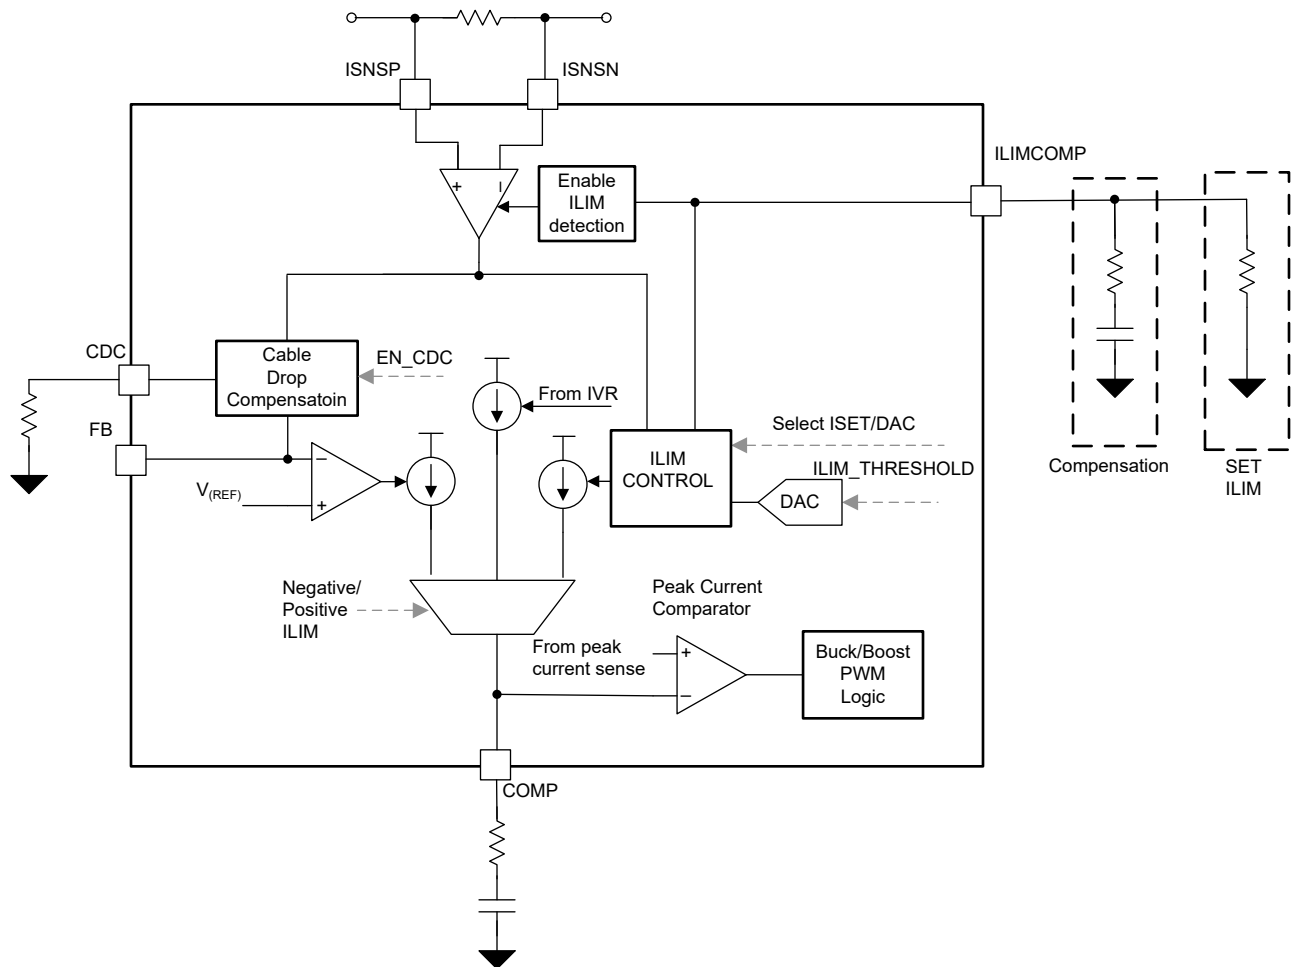

Figure 8-16. Current Monitor Functional Block Diagram

8.3.10.2 Output Current Limitation

In this configuration the current sense has an internal feedback to the peak current limit of the device. The ILIM circuit regulates the peak current limit down as long as the differential voltage between ISNSP and ISNSN exceeds the internal offset voltage of the ILIM circuit. The ILIM threshold can be set via the register programming or via the an ISET resistor in the ILIMCOMP pin.

If the threshold for the current limit is set by the internal DAC the bandwidth of the current limit can be optimized for different with a resistor and capacitor on the ILIMCOMP - pin. It is recommended to select the compensation bandwidth according the following: TBD -equations

If the current limit threshold is selected by a resistor a internal comparator monitors the voltage on the ILIMCOMP pin. If the voltage exceeds the ISET threshold the current limit is reached. The threshold voltage for ISET can be calculated with: $V_{(ISET)} = (V_{(ISNSP)} - V_{(ISNSN)}) \times gm_{(ILIMCOMP)} \times R_{(ILIMCOMP)}$

The current through the sense resistor can be monitored by the CDC pin simultaneously.

The read-out register value of the "ILIM_THRESHOLD" control register is clamped for the lower and for the upper limit of the register range.

- The reg. readout value is clamped to the lowest clamp current (e.g. 500 mA) if a register value below the value of clamp current been written in before.
- The reg. readout value is clamped to the highest clamp current if a register value above the highest value of clamp current has been written in before.

8.3.10.3 Output Current Monitor

The current through the sense resistor can be monitored by the CDC pin simultaneously and has no impact to a configured current limit via the ILIMCOMP pin. If the limiter is disabled (IMON_LIMITER_EN = 0b0) both pins provide a proportional current to the differential voltage of ISNSP/N with. The Voltage can be calculated with

$$V_{(CDC)} = (V_{(ISNSP)} - V_{(ISNSN)}) \times gm_{(CDC)} \times R_{(CDC)} \quad (4)$$

$$V_{(ILIMCOMP)} = (V_{(ISNSP)} - V_{(ISNSN)}) \times gm_{(ILIMCOMP)} \times R_{(ILIMCOMP)} \quad (5)$$

8.3.11 Oscillator Frequency Selection

The LM51772 has a low tolerance internal trimmed oscillator. With the RT pin left open, the oscillator frequency is 75 kHz. With the RT pin grounded, the switching frequency is at the maximum of 2.5 MHz. The oscillator frequency can be programmed up or down by connecting a resistor from the RT pin to ground. To calculate the RT resistor for a specific oscillator frequency, use [Equation 6](#).

$$R_{(RT)} = \left(\frac{1}{f_{(sw)}} - 18ns \right) \times 31.5 \frac{G\Omega}{s} \quad (6)$$

The RT pin is regulated to 0.75 V by an internal voltage source when the device is in active mode. Therefore, the switching frequency can be dynamically changed during operation by changing the current flowing through the resistor. [Figure 8-17](#) and [Figure 8-18](#) show two examples for changing the frequency by the switching the resistor value or applying a external voltage source through a resistor. It is not recommended to connect any additional capacitance directly to the RT pin.

Figure 8-17. Frequency Hopping Example

Figure 8-18. Dynamic Frequency Changing Example

8.3.12 Frequency Synchronization

The device features an internal phase locked loop (PLL), which is designed to transition the switching frequency seamlessly between the frequency set by the RT pin and the external frequency synchronization signal. If no external frequency is provided, the RT pin sets the center frequency of the PLL. The external synchronization signal can change the switching frequency $\pm 50\%$. To ensure low quiescence current, the input buffer of the SYNC pin is disabled if no valid sync frequency, that is a frequency signal outside the recommended synchronization range is applied.

The $f_{(SW)}$ synchronization stops if the device enters power save mode or μ Sleep operation, if enabled. Once the converter enters the PWM operation again, the device re-syncs to a pin signal. The synchronization timings are given in Figure 8-20

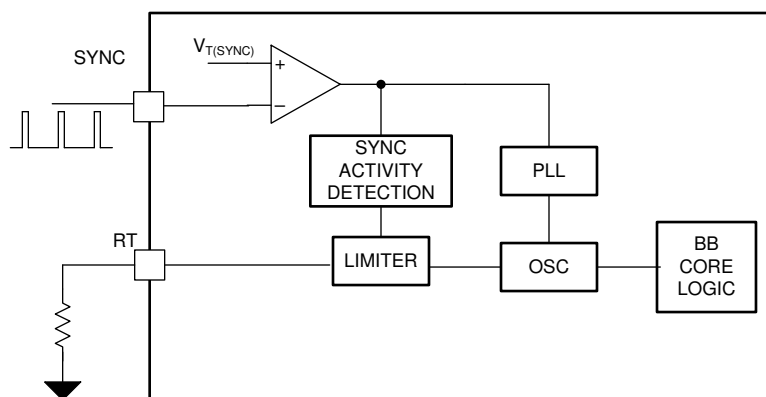

Figure 8-19. Main Oscillator Functional Block Diagram

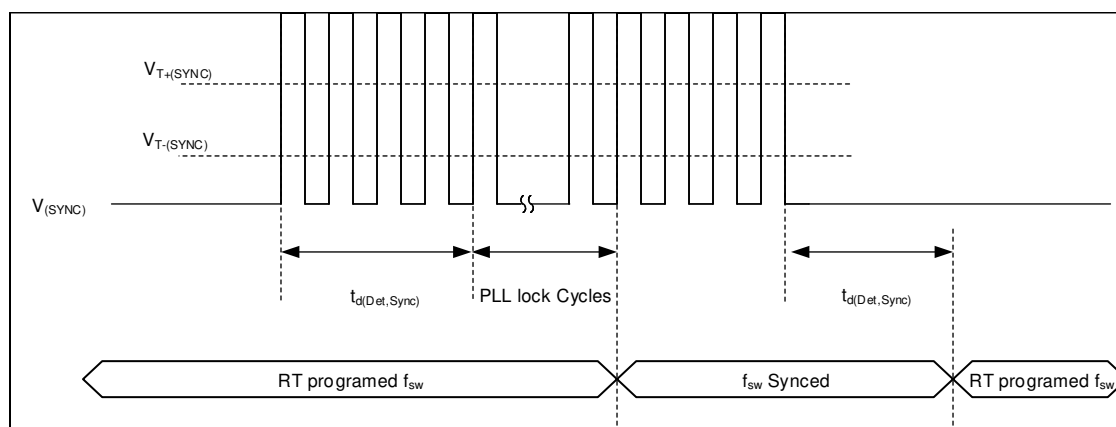

Figure 8-20. Timing Diagram SYNC Function

The sync pin can be programmed through I2C or config pin CFG2 as input or output.

8.3.13 Output Voltage Tracking

There are two kinds of output voltage tracking features integrated in the device.

- Analog voltage tracking function through the SS/ATRK pin
- Digital voltage tracking function through the DTRK pin

8.3.13.1 Analog Voltage Tracking

For the analog output voltage tracking, an external applied voltage overwrites the reference voltage for the output regulation loop. Although it is possible, it is not recommended to apply this voltage before the soft start is finished because the soft-start ramp time and, therefore, the input current during the start-up is changed.

As the internal error amplifier is designed to use the lowest reference input voltage, the applied voltage on the SS/ATRK pin is only effective for voltages lower than the V_{ref} of the feedback pin. Hence, the maximum voltage for the output is determined by the resistor network on the FB pin.

If the analog voltage tracking is used to start-up the converter voltage a change at the mode pin from high to low or low to high will indicate the logic that the soft-start is completed.

8.3.13.2 Digital Voltage Tracking

The DTRK input of the LM51772 directly modulates the internal reference voltage. This function activates if the voltage on the DTRK pin is higher than the rising threshold of $V_{T(DTRK)}$ and a PWM signal in the recommended frequency is applied to the pin.

The maximum output voltage during digital tracking cannot exceed the nominal reference voltage for the FB resistor divider. The applied PWM signal reduces the internal reference voltage in relation with the duty cycle on the DTRK pin. A small duty cycle means less output voltage and a high duty cycle of the PWM input represents a high output voltage. For example, a duty cycle of 30% causes a output voltage of 30% of the selected voltage by the FB divider resistors.

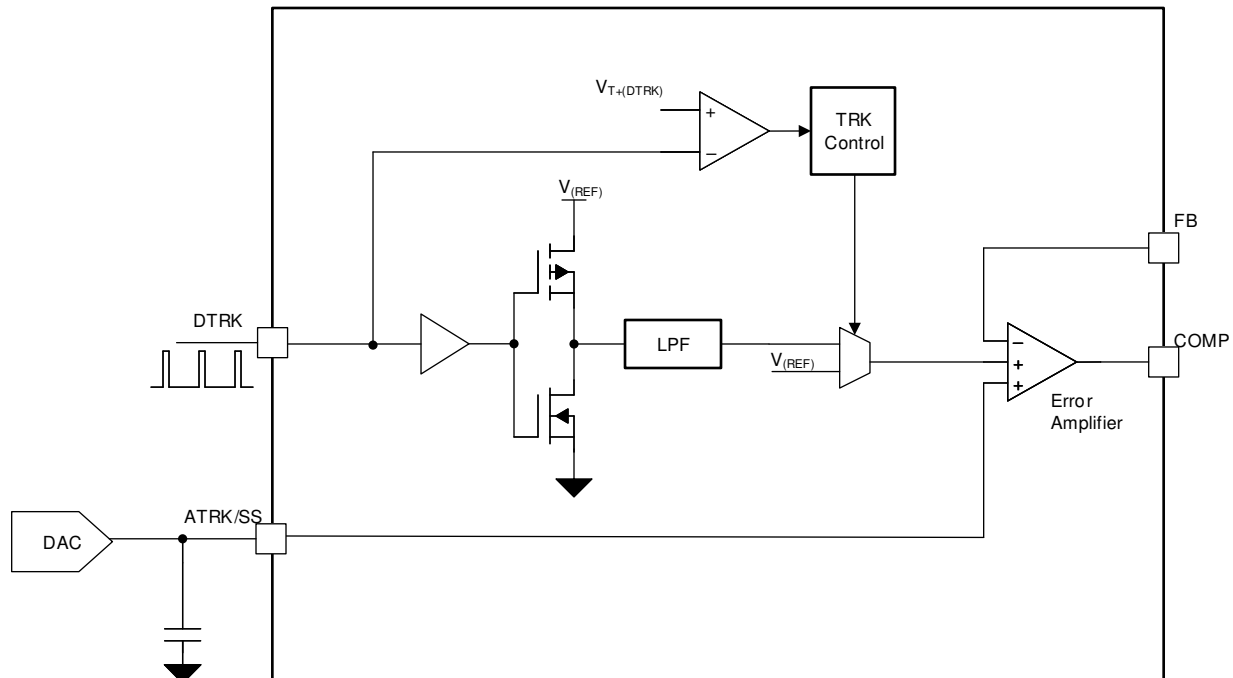

Figure 8-21. Output Voltage Tracking Functional Block Diagram

8.3.14 Slope Compensation

The LM51772 provides slope compensation to ensure stable operation and the best transient performance over a wide operating range. According to peak current mode control theory, slope compensation is required at operation with duty cycle greater than 50%.

First a correction factor needs to be calculated from [Equation 7](#)

$$m_{SC} = \frac{R_{CS}}{f_{SW} \times L} \times 625 \quad (7)$$

Based on the calculated correction factor the slope compensation can be programmed through I2C or by connecting a resistor to ADDR/Slope pin. See [Table 8-2](#) for selecting the resistor value based on the slope compensation correction factor.

8.3.15 Configurable Soft Start

The soft-start feature allows the regulator to gradually reach the steady-state operating point, thus reducing start-up stresses and surges.

The LM51772 features an adjustable soft start that determines the charging time of the output. The soft-start feature limits inrush current as a result of high output capacitance to avoid an over-current condition.

At the beginning of the soft-start sequence, the SS voltage is 0 V. If the SS pin voltage is below the feedback reference voltage, V_{REF} , the soft-start pin controls the regulated FB voltage and the internal soft-start current source gradually increases the voltage on an external soft-start capacitor connected to the SS pin, resulting in a gradual rise of the output voltage and FB pin. Once the voltage on the SS exceeds the internal reference voltage, the soft-start interval is complete and the error amplifier is referenced to V_{REF} .

The soft-start time (t_{ss}) is given by:

$$C_{SS} = \frac{I_{SS} \times t_{ss}}{V_{REF}} \quad (8)$$

The soft-start capacitor is internally discharged when the converter is disabled because of the following:

- EN/UVLO falling below the operating threshold
- VCC falling below the VCC UV threshold
- The device is in hiccup mode current limiting.
- The device is in thermal shutdown.

8.3.16 Drive Pin

The device features a high voltage drive pin (DRV1) to support an input or output disconnect FET. This in can be also used as a driver for a charge pump output to do a reverse polarity protection using an external n-channel FET. The supply for this pin can be selected by R2D and I2C configurations.

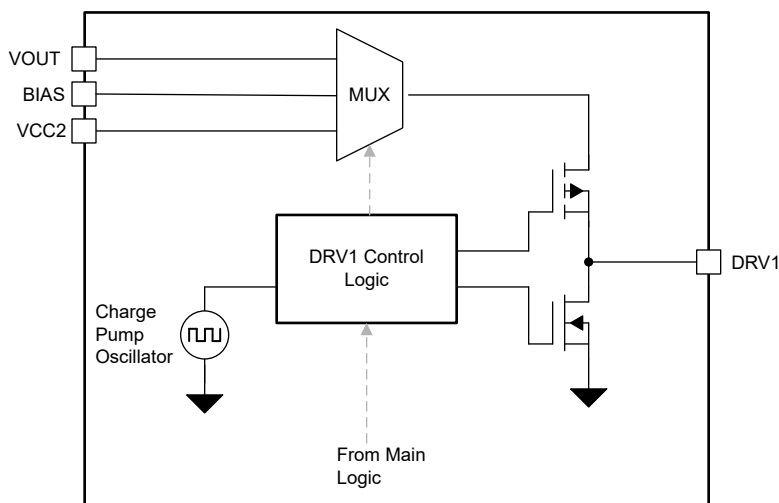

Figure 8-22. Functional Block Diagram - DRV pin

The following configurations are possible with to support with the DRV1 pin:

1. Open drain output.
2. High Voltage Push-pull supplied by VOUT
3. High Voltage Push-pull supplied by VBIAS
4. CP drive pin supplied by the VCC2

The sequencing of the DRV pin is depending on the R2D/I2C setting an given by the state diagram XREF

8.3.17 Dual Random Spread Spectrum – DRSS

The device provides a digital spread spectrum, which reduces the EMI of the power supply over a wide frequency range. This function is enabled by the CFG pin. When the spread spectrum is enabled, the internal modulator dithers the internal clock. When an external synchronization clock is applied to the SYNC pin, the internal spread spectrum is disabled. DRSS combines a low frequency triangular modulation profile with a high frequency cycle-by-cycle random modulation profile. The low frequency triangular modulation improves performance in lower radio frequency bands (for example, AM band), while the high frequency random

modulation improves performance in higher radio frequency bands (for example, FM band). In addition, the frequency of the triangular modulation is further modulated randomly to reduce the likelihood of any audible tones. To minimize output voltage ripple caused by spread spectrum, duty cycle is modified on a cycle-by-cycle basis to maintain a nearly constant duty cycle when dithering is enabled.

Figure 8-23. Dual Random Spread Spectrum

8.3.18 Gate Driver

The LM51772 features four internal logic-level nMOS gate drivers. The drivers maintain the high frequency switching of both half bridges needed for a buck-boost operation. If the device is in boost or buck mode, the other half bridge high-side switch needs to be permanent on. The internal gate drivers support this by sharing the current from the other half bridge, which is switching. Therefore, a minimum of quiescent current can be assured as no additional charge pump is needed. Due to the high drive current, it can support a wide range of external power FETs as well as a parallel operation of them.

The LO and HO outputs are protected with a shoot-through protection, which ensures that both outputs are not turned on at the same time. If the PWM modulation logic of the buck-boost turns the LOx pin off, the HOx pin is not turned on until the following are true:

1. A minimum internal transition time ($t_{t(dead)}$) is reached.
2. The voltage on the LOx pin drops below the detection threshold $V_{TH(GATEOUT)}$.

This behavior is maintained and vice versa if the HOx pin turns off first.

The high-side supply voltage for the gate driver are monitored by an additional bootstrap UVLO comparator. This comparator monitors the differential voltage between SWx and HBx. If the voltage drops below the threshold the buck-boost converter operation turns off. The device restarts automatically once the positive going threshold is reached with the soft-start scheme.

Additionally, the LM51772 monitors the upper voltage between SWx and HBx. If this voltage exceeds the threshold voltage of the clamping circuit, it activates an internal current source to pull the voltage down.

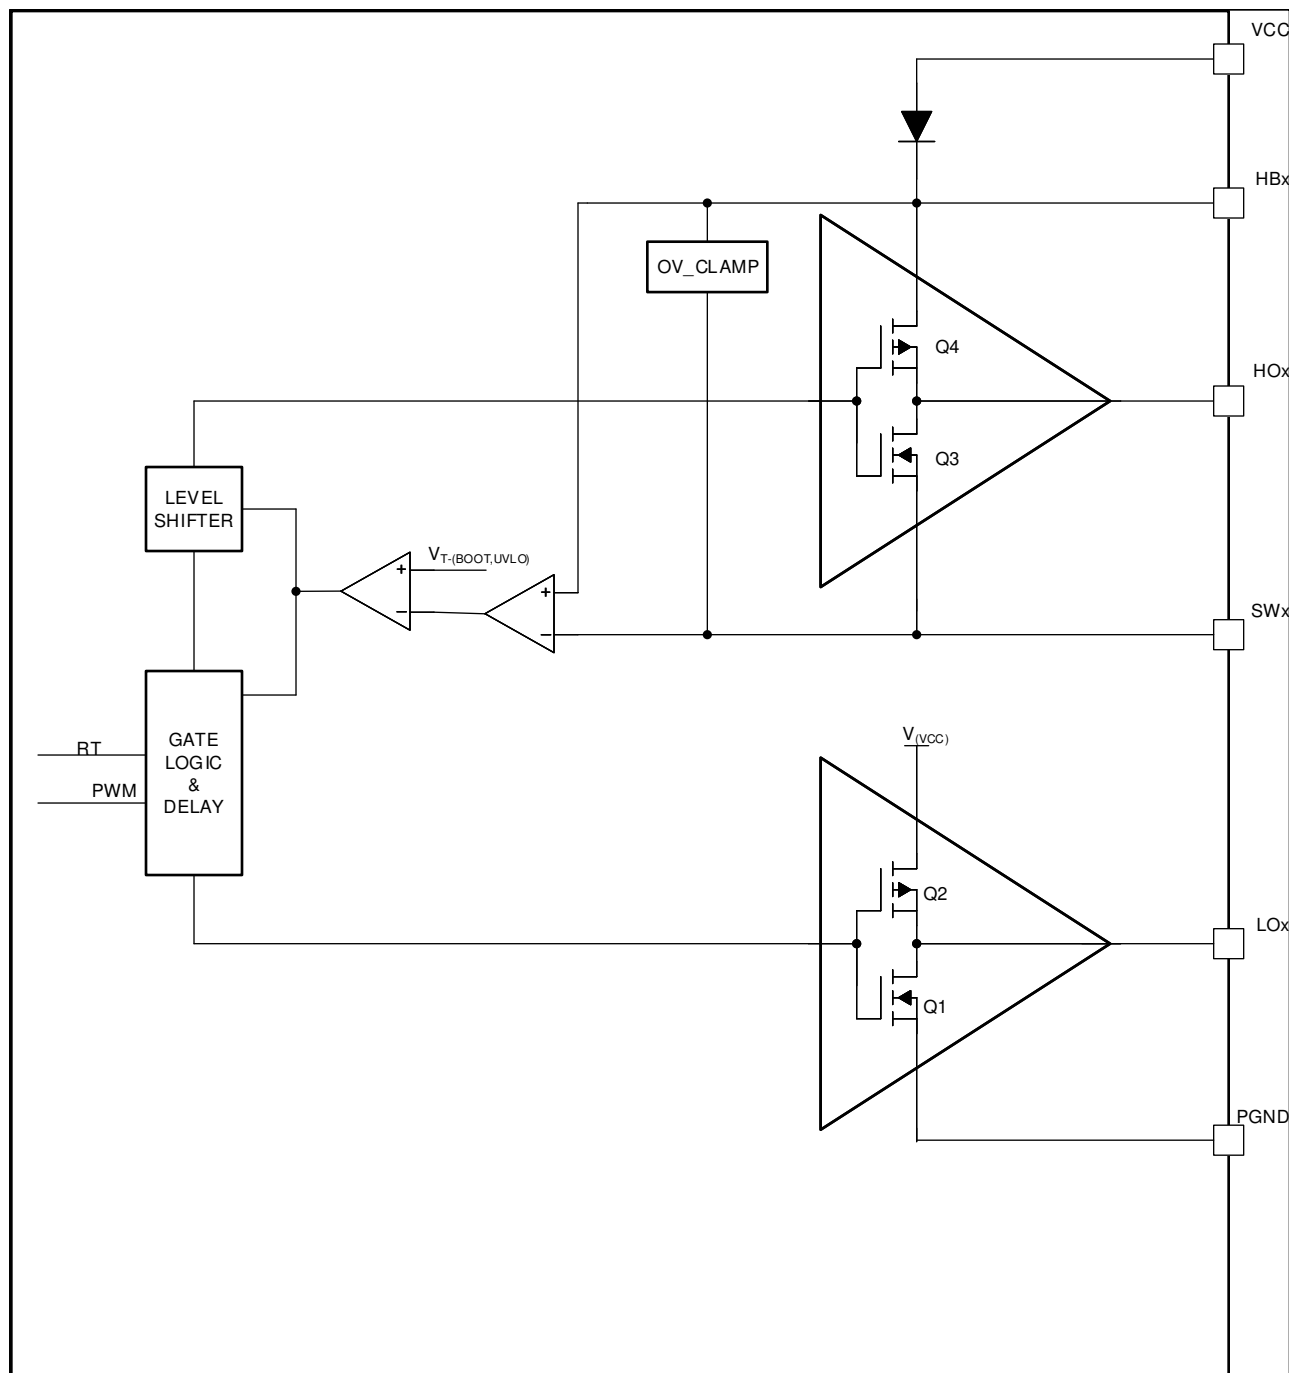

Figure 8-24. Functional Block Diagram Gate Driver

8.3.19 Cable Drop Compensation (CDC)

The cable drop compensation feature helps to keep the output voltage at the nominal value over a wide range of load current without the need for additional remote sensing. The voltage drop compensation measures the current and feeding back the current information to the internal voltage control loop of the converter.

If enabled, the gm stage of the current monitor sensor (ISNSP/N) sends a proportional current to the CDC pin. The voltage across the CDC pin is applied as an offset to the nominal output voltage. It is recommended to select the resistor value on the CDC-pin not to exceed 1 V. The Equation below:

$$V_{(CDC)} = (V_{(ISNSP)} - V_{(ISNSN)}) \times gm_{(CDC)} \times R_{(CDC)} \quad (9)$$

The CDC function can operate for the internal or external feedback divider with the same behavior.

To achieve a accurate operation for the desired range cable drop compensation the gain of the CDC offset can be programmed by the CDC_GAIN register bits.

The CDC function operates equally with the external Feedback divider. It's recommended to use a 100kΩ feedback divider top resistance.

The figure below shows the control curve of the CDC feature.

Figure 8-25. Vo Offset vs. CDC voltage

8.3.20 CFG-pin and R2D Interface

The LM51772 has four register to digital channels, where the CFG1 is allocated to the ADDR/SLOPE -pin. The channels CFG3 and CFG4 are ultiplexed with the SDA/SCL pins.

The resistor selection on the CFG pins is read and latched during the power-up sequence of the device. The selection cannot be changed until the voltage on the EN or UVLO reaches the falling threshold or VCC voltage drops below the $V_{CCT-(UVLO)}$ threshold. The [Table 8-2](#) shows the possible device configurations versus the different resistor values on the CFG pins.

Table 8-2. ADDR/Slope Pin (R2D-CH1) Configuration Overview

8.3.21 Advanced Monitoring Features

8.3.21.1 Overview

The device features a status register in which the current operation status can be pulled by the interface.

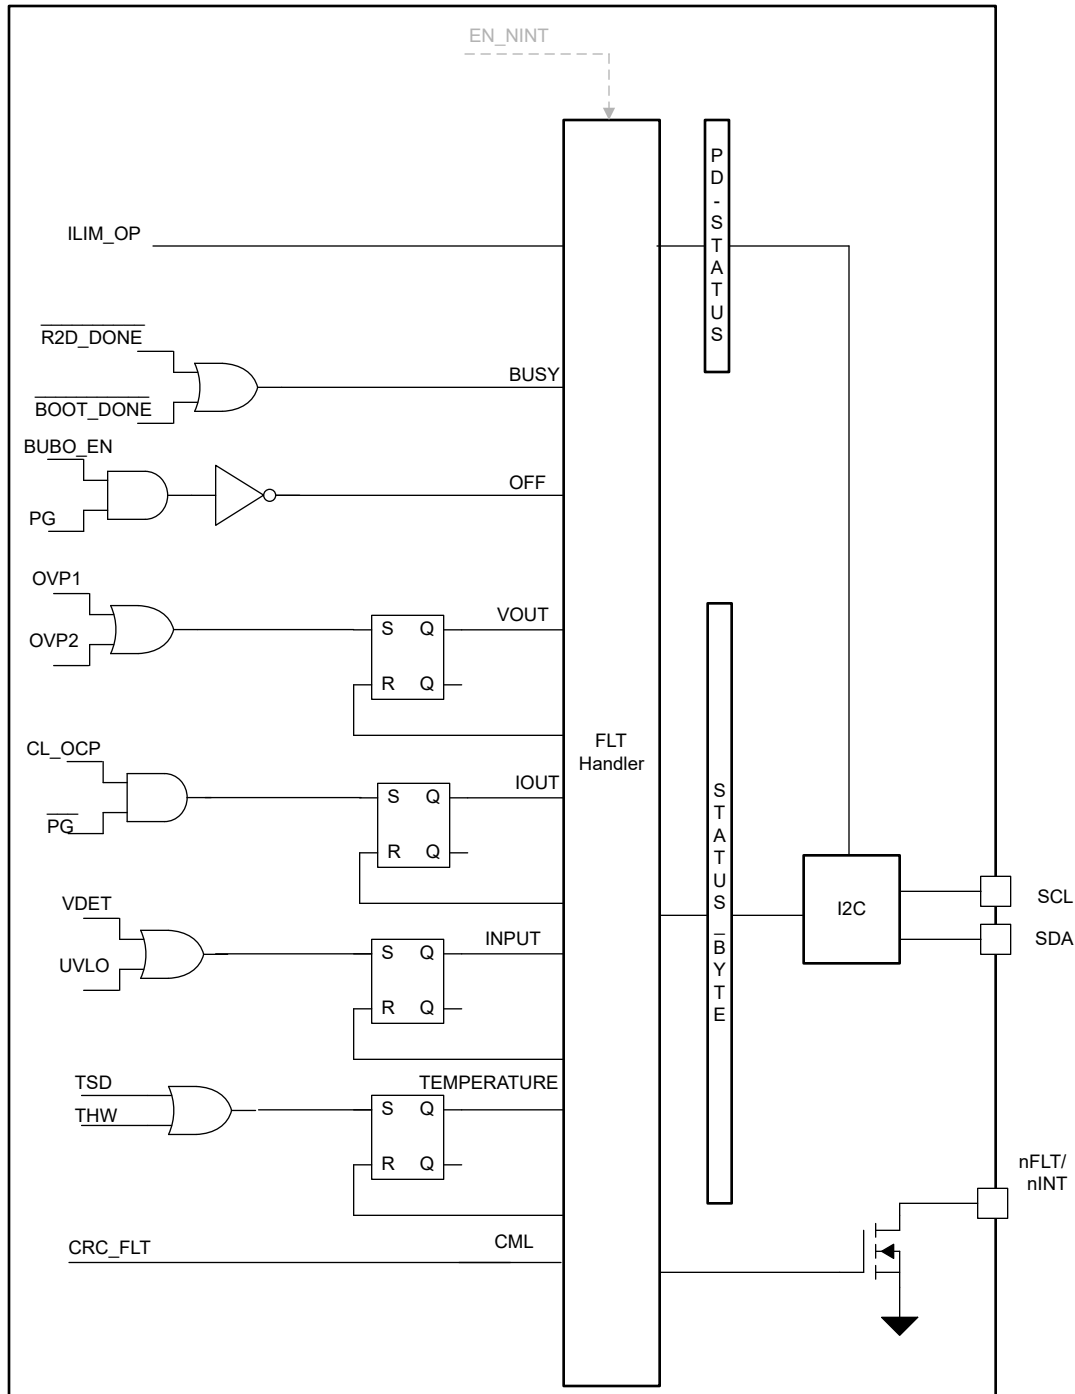

Figure 8-26. Functional Block Diagram Fault Handler

8.3.21.2 BUSY

BUSY

If the device register field is busy or in use by another instance this bit is high. Writing via the I²C interface not recommended during busy flag high. This bit is only observed after the device start-up

8.3.21.3 OFF

OFF

Is high if the device is not providing a high enough output voltage ($V_{(VOUT)} < V_{T+(PG)}$). This bit is also high if the converter is turned off by system input. This bit is only observed after the device start-up

8.3.21.4 VOUT

Output voltage over voltage threshold (OVP1, OVP2) was exceeded. This error gets latched until the register is cleared or a power cycle happens

8.3.21.5 IOUT

Over current protection of peak current sensor is reached. This error gets latched until the register is cleared or a power cycle happens

8.3.21.6 INPUT

The input voltage detection (VDET) or the UVLO resistor senses voltage is below the falling threshold. This error gets latched until the register is cleared or a power cycle happens

8.3.21.7 TEMPERATURE

The device has entered TSD state or the programmable thermal warning threshold is reached. This error gets latched until the register is cleared or a power cycle happens

8.3.21.8 CML

The device detects an internal logic fault i.e. the NVM memory check-sum has detected data retention event.

8.3.21.9 OTHER

OTHER

unused

8.3.21.10 ILIM_OP

This signal is enabled together with the current limiter. If the current limiter is off the signal is low. If the programmed (via I²C or ISET) current limit threshold is reached the signal goes high. The PD-STATUS byte is instantaneously changing with the ILIM_OP signal. The input signal gets de-glitch in the analog domain.

8.3.21.11 nFLT/nINT Pin output

If the bit EN_NINT is set to 0b0 the nFLT/nINT pin indicates all faults that is reported by the signal to the in the STATUS byte.

After a restart of the converter operation or in case the failure mode disappears the nFLT pin will go back to HighZ. The input signals to the STATUS-BYTE and therefore the nFLT/nINT pin are de-glitched. Because of this the maximum reaction time of the FLT pin is given by $t_{d(nFLT-PIN)}$

It is not recommended to change the EN_NINT dynamically during operation, but during the CONV_OFF state.

In case the EN_NINT = 0b1 the nFLT/nINT pin acts as interrupt pin. A change of the instantaneous signal to the STATUS_BYTE as well as the inputs to the USB_PD_STATUS_0 toggles the pin.

8.3.21.12 Status Byte

The following methods can be used to clear a fault

1. Perform an I²C write to the CLEAR_FAULTS byte.
2. Perform an I²C read to the CLEAR_FAULTS byte.
3. Perform an I²C write to the STATUS_BYTE where a fault is indicated with a '1' and clear this bit by setting it to '1'. This allows to write an old STATUS_BYTE to clear the old faults for diagnosis.

8.3.22 Protection Features

8.3.22.1 Thermal Shutdown (TSD)

To avoid the case of a thermal damage of the device the temperature of the die is monitored. The device will stop operation once the sensed temperature rises over the thermal shutdown threshold. After the temperature drops below the thermal shutdown hysteresis the TSD signal goes back to normal and the converter will return to normal operation according to the main FSM definition.

8.3.22.2 Over Current Protection

The device features a hiccup mode short circuit protection to avoid excessive power dissipation in the die or at the fault of the application in the System. The CL_OCP triggers if the peak current sensing voltage between CSA-pin and CSB-pin is exceeded.

If enabled the protection will stop the converter operating and re-start the converter in case a short is event is detected.

The bit HICCUP_EN in the NVM register enables the OCP.

8.3.22.3 Output Over Voltage Protection 1 (OVP1)

This over voltage protection monitors the voltage of the FB-pin

As this threshold is referenced to the $V_{(REF)}$ the OVP1 is still working if one of the tracking features has changed the V_o target value. The OVP protection can be disabled during the V_o change of one of the V_o tracking features.

The converter maintains in regulation even the OVP1 threshold triggers.

The OVP1 is disabled during uSleep to avoid additional leakage current. The OVP signal gets masked that no fault is indicated from this signal during the uSleep operation.

This protection is disabled during the soft-start procedure and if the iFB is used instead of the ext. FB

8.3.22.4 Output Over Voltage protection 2 (OVP2)

This feature shall avoid any damage to the device in case the ext. feedback pin is not working properly i.e is shorted

The over voltage protection is realized by the converter core and reference system. The device main logic only monitors the OVP 2 function the converter logic will take an appropriate measure (e.g. emergency skip mode) to avoid a further increase of the output voltage.

If the output voltage threshold $V_{T+(OVP2)}$ is reach on the VOUT-pin the buck-boost core logic disables the converter power stage and enters a high impedance state at the switch nodes. If the output voltage falls back under this threshold the convert operation is resumed

Due to wide recommended operation range, the OVP2 protection of lower V_o application is limited. Therefore the OVP2 threshold is programmable by the V_OVP2 register field.

For power savings e.g. in burst mode or uSleep the OVP2 circuit can be turned off. In this case it need to be ensured that a fault on the feedback or any other mechanism enter- re-enter sleep will not impact the correct function of OVP

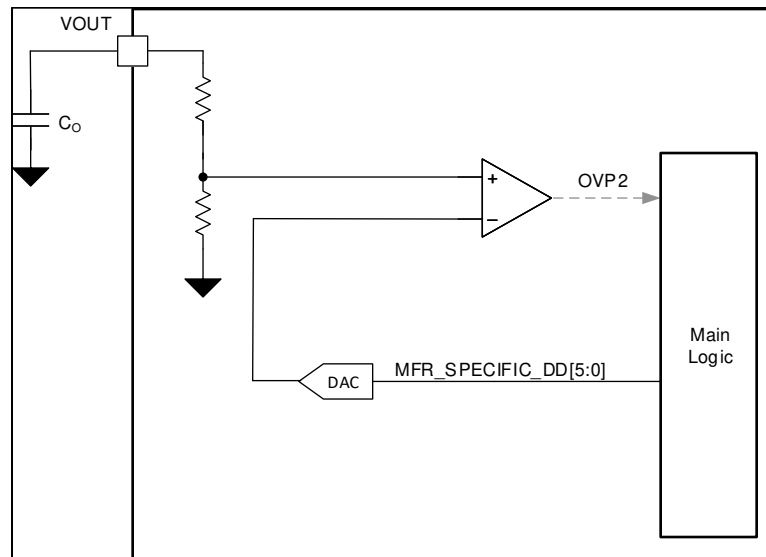

Figure 8-27. Functional Block Diagram OVP2

8.3.22.5 Input Voltage Protection (IVP)

Input Voltage Protection (IVP)

The input over voltage protection is realized by the converter core modulation scheme. It shall avoid any damage to the device in case the current flows from the output to the input and the input source cannot sink current e.g. a diode in the supply path. If the converter forced PWM mode is active the current can go negative until to the sink current limit. Once the input voltage threshold $V_{T+(IVP)}$ is reached on the VIN-pin the protection disables the forced PWM mode and only allows current to flow from VIN to VOUT. After the input voltage drops under the input voltage protection threshold, the fPWM mode can be activated again.

The threshold for the $V_{T+(IVP)}$ is programmable via the V_IVP register field and can be disabled through the EN_IVP bit.

8.3.22.6 Input Voltage Regulation (IVR)

The input over voltage protection the IVR regulates the input voltage using the current monitor block. The threshold for the target voltage is programmed by the V_IVR register. The IVR function is enabled once EN_IVP and EN_IVR set to 0b1. The fPWM needs to be enabled the reverse current to charge the input. If Mode pin is pulled low the IVR operation is paused until the fPWM is enabled again.

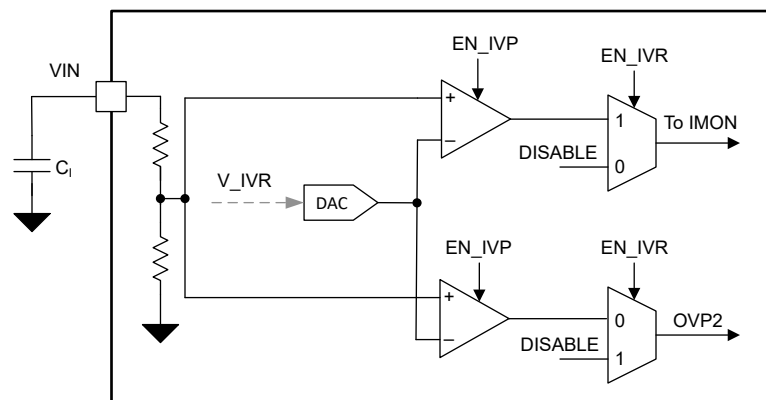

Figure 8-28. Functional Block Diagram IVP/IVR

8.3.22.7 Power Good

The device features a power good detection. The internal PG signal is used for the monitoring function.

As during soft-start the signal for the PG is not available the power good function is not available during this state.

8.3.22.8 Boot-strap Under Voltage Protection

The high side supply voltage for the gate driver and as well for the are monitored by an additional boot strap UVLO comparator. This comparator monitors the differential voltage between SWx and HBx. This protection supports the two modes in the following manner.

1. If the measured voltage drops below $V_{TH(BST_UV)}$ in fPWM mode the converter stops operation after a trimmed amount of switching cycles.
2. In PSM i.e. 2 switching phase buck-boost operation, the BOOT_UV triggers switching of the converter to re-fresh the boot strap voltage. If the initiated switching does not bring up the BOOT_UV after the trimmed amount of re-fresh cycles the fPWM protection deactivates the converter operation.

I

8.3.22.9 Boot-strap Over Voltage Clamp

To protect the ext. FET gate and the internal gate drive circuit the charge sharing circuit of the gate driver features an over voltage clamp. If the voltage goes above $V_{TH(BST_OV)}$ the linear regulator from the boot strap charge sharing sinks a current from HBx to SWx as long as the voltage is above the threshold.

8.3.22.10 CRC - CHECK

To ensure data integrity of the NVM the device features a CRC- algorithm to generate a check-sum for the data stored in the device NVM.

The check-sum gets generated and stored to the separate NVM register automatically with the OTP programming process.

After the NVM boot phase the CRC algorithm compares the check-sum of the loaded registers with the check-sum stored in the NVM register generated during the production tests. If the two values is not equal to device is not allowed to exit the CONV_OFF state.

8.4 Device Functional Modes

8.4.1 Overview

The device contains a digital logic core that controls the functional behavior. The logic and internal oscillator are turned off to save current in case no interrupt of a converter internal signal occurs.

8.4.2 Logic State Description

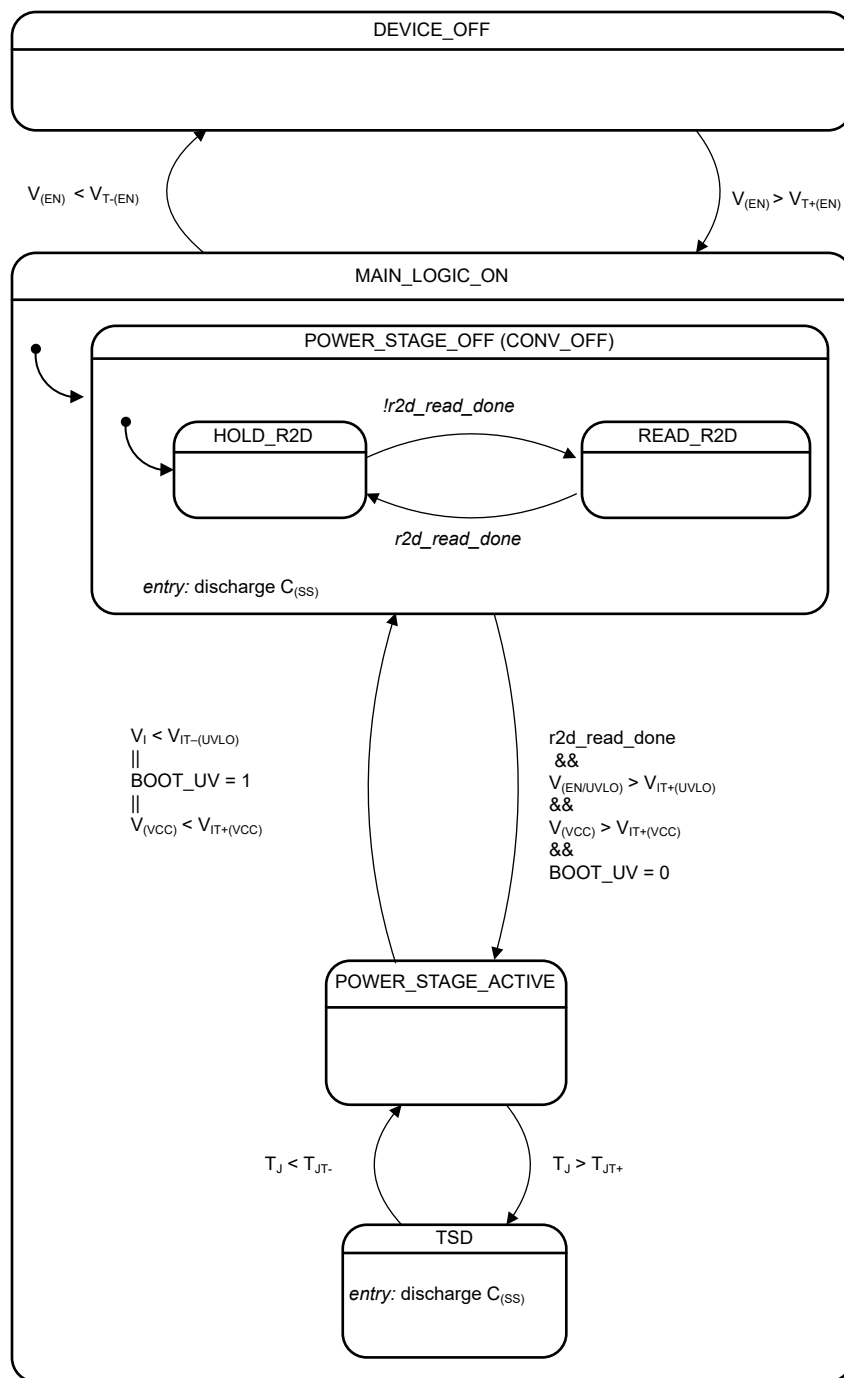

Figure 8-29. State Diagram

8.5 Programming

8.5.1 I²C Bus Operation

The I²C bus is a communications link between a controller and a series of target devices. The link is established using a two-wired bus consisting of a serial clock signal (SCL) and a serial data signal (SDA). The serial clock is sourced from the controller in all cases where the serial data line is bi-directional for data communication between the controller and the target terminals. Each device has an open-drain output to transmit data on the serial data line (SDA). An external pull-up resistor must be placed on the serial data line

to pull the drain output high during data transmission. The device hosts a target I²C interface that supports standard-mode, fast-mode and fast-mode plus operation with data rates up to 100 kbit/s, 400 kbit/s and 1000 kbit/s respectively and auto-increment addressing compatible to I²C standard 3.0.

The 7 bit target address of this device is 0x6A if the ADDR/SLOPE pin is pulled to GND and 0x6B if the pin is connected to VCC2

Data transmission is initiated with a start bit from the controller as shown in the figure below . The start condition is recognized when the SDA line transitions from high to low during the high portion of the SCL signal. Upon reception of a start bit, the device will receive serial data on the SDA input and check for valid address and control information. If the target address bits are set for the device, then the device issues an acknowledge pulse and prepares the receive of register address and data. Data transmission is completed by either the reception of a stop condition or the reception of the data word sent to the device. A stop condition is recognized as a low to high transition of the SDA input during the high portion of the SCL signal. All other transitions of the SDA line must occur during the low portion of the SCL signal. An acknowledge is issued after the reception of valid address, sub-address and data words. The I²C interfaces will auto-sequence through register addresses, so that multiple data words can be sent for a given I²C transmission.

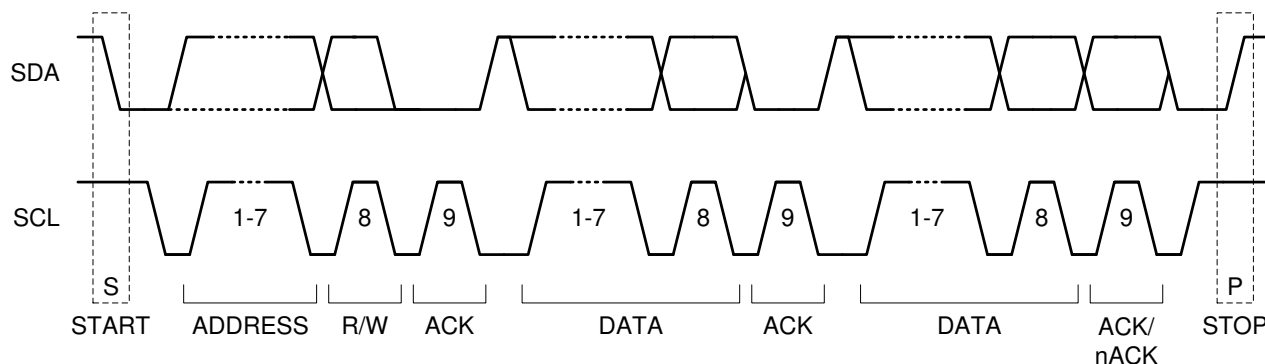

Figure 8-30. I²C START / STOP / ACKNOWLEDGE Protocol

Figure 8-31. I²C Data Transmission Timing

Figure 8-32. I²C Data Transmission Timing for maximum rise/fall times.

8.5.2 Clock Stretching

Clock stretching is not supported. If the device is addressed while busy and not able to process the received data, it does not acknowledge the transaction. This may happen if the controller initiates an I²C transaction while the device is in BOOT state.

8.5.3 Data Transfer Formats

The device supports four different read/write operations:

- Single read from a defined register address.
- Single write to a defined register address.
- Sequential read starting from a defined register address
- Sequential write starting from a defined register address

8.5.4 Single READ from a Defined Register Address

[Single READ from a defined register address](#) shows the format of a single read from a defined register address. First, the controller issues a start condition followed by a seven-bit I²C address. Next, the controller writes a zero to signify that it conducts a write operation. Upon receiving an acknowledge from the target the controller sends the eight-bit register address across the bus. Following a second acknowledge the device sets the internal I²C register number to the defined value. Then the controller issues a repeat start condition and the seven-bit I²C address followed by a one to signify that it conducts a read operation. Upon receiving a third acknowledge, the controller releases the bus to the device. The device then returns the eight-bit data value from the register on the bus. The controller does not acknowledge (nACK) and issues a stop condition. This action concludes the register read.

Figure 8-33. Single READ from a defined register address

8.5.5 Sequential READ Starting from a Defined Register Address

A sequential read operation is an extension of the single read protocol and shown in [Sequential READ starting from a defined register address](#). The controller acknowledges the reception of a data byte, the device auto

increments the register address and returns the data from the next register. The data transfer is stopped by the controller not acknowledging the last data byte and sending a stop condition.

Figure 8-34. Sequential READ starting from a defined register address

8.5.6 Single WRITE to a Defined Register Address

[Single WRITE to defined register address](#) shows the format of a single write to a defined register address. First, the controller issues a start condition followed by a seven-bit I²C address. Next, the controller writes a zero to signify that it wishes to conduct a write operation. Upon receiving an acknowledge from the target, the controller sends the eight-bit register address across the bus. Following a second acknowledge the device sets the I²C register address to the defined value and the controller writes the eight-bit data value. Upon receiving a third acknowledge the device auto increments the I²C register address by one and the controller issues a stop condition. This action concludes the register write.

Figure 8-35. Single WRITE to defined register address

8.5.7 Sequential WRITE Starting at a Defined Register Address

A sequential write operation is an extension of the single write protocol and shown in [Sequential WRITE starting at a defined register address](#). If the controller doesn't send a stop condition after the device has issued an ACK, the device auto increments the register address by one and the controller can write to the next register.

Figure 8-36. Sequential WRITE starting at a defined register address

8.6 LM51772 Registers

Table 8-6 lists the memory-mapped registers for the LM51772 registers. All register offset addresses not listed in **Table 8-6** should be considered as reserved locations and the register contents should not be modified.

Table 8-6. LM51772 Registers

Address	Acronym	Register Name	Section
0x3	CLEAR_FAULTS	CLEAR_FAULTS	Go
0xA	ILIM_THRESHOLD	ILIM_THRESHOLD	Go
0xC	VOUT_TARGET1_LSB	VOUT_TARGET1_LSB	Go
0xD	VOUT_TARGET1_MSB	VOUT_TARGET1_MSB	Go
0x21	USB_PD_STATUS_0	USB_PD_STATUS_0	Go

9 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

9.1 Application Information

The LM51772 is a wide input voltage, synchronous, non-inverting buck-boost controller, suitable for applications that need a regulated output voltage from an input supply that can be higher or lower than the output voltage. To expedite and streamline the process of designing the external circuits and select the components, a comprehensive [quickstart calculator](#) is available for download to assist the designer with component selection for a given application.

9.2 Typical Application

Figure 9-1. Simplified Schematic of a Typical Application

9.2.1 Design Requirements

Table 9-1 shows the intended input, output, and performance parameters for a typical design example.

Table 9-1. Design Parameters

Parameter	Value
V_I minimum	9 V
V_I typical = V_I start-up	19.5 V
V_I maximum	48 V
V_O nominal	20 V
P_O maximum	100 W

9.2.2 Detailed Design Procedure

9.2.2.1 Custom Design with WEBENCH Tools

[Click here](#) to create a custom design using the LM51772 device with the WEBENCH® Power Designer.

1. Start by entering your V_{IN} , V_{OUT} and I_{OUT} requirements.
2. Optimize your design for key parameters like efficiency, footprint and cost using the optimizer dial and compare this design with other possible solutions from Texas Instruments.
3. WEBENCH Power Designer provides you with a customized schematic along with a list of materials with real time pricing and component availability.
4. In most cases, you will also be able to:
 - Run electrical simulations to see important waveforms and circuit performance,
 - Run thermal simulations to understand the thermal performance of your board,
 - Export your customized schematic and layout into popular CAD formats,
 - Print PDF reports for the design, and share your design with colleagues.
5. Get more information about WEBENCH tools at www.ti.com/webench.

9.2.2.2 Frequency

The switching frequency of LM51772 is set by an R_T resistor connected from the RT/SYNC pin to AGND. The R_T resistor required to set the desired frequency is calculated using [Equation 10](#). A 1% standard resistor of 51.0 k Ω is selected for $f_{SW} = 600$ kHz.

$$R_{(RT)} = \left(\frac{1}{f_{SW}} - 18\text{ns} \right) \times 31.5 \frac{\text{G}\Omega}{\text{s}} \quad (10)$$

9.2.2.3 Feedback Divider

The feedback voltage divider is found with [Equation 11](#):

$$R_{FB,top} = (V_{(VOUT)} - V_{(REF)}) \times R_{FB,bot} \quad (11)$$

For the 20-V output, an upper resistor of 82.0 k Ω and a lower resistor of 4.3 k Ω have been selected.

[FB Pin Resistor Divider Examples with \$R_{FB,top} = 71.5\$ k \$\Omega\$](#) shows an overview of a possible selection for the feedback divider resistors over common output voltages.

Table 9-2. FB Pin Resistor Divider Examples with $R_{FB,top} = 71.5$ k Ω

V_O – Target	$R_{FB,bot}$ – Calculation	$R_{FB,bot}$ – E48 Series	V_O Nominal	Error from FB Resistor
5 V	17.9 k Ω	17.8 k Ω	5.02 V	0.3%
9 V	8.94 k Ω	9.09 k Ω	8.87 V	-1.5%
12 V	6.50 k Ω	6.59 k Ω	12.02 V	0.1%
16 V	4.77 k Ω	4.87 k Ω	15.68 V	-2.0%
24 V	3.11 k Ω	3.16 k Ω	23.63 V	-1.6%
28 V	2.65 k Ω	2.61 k Ω	28.39 V	1.4%
36 V	2.04 k Ω	2.05 k Ω	35.88 V	-0.3%
42 V	1.74 k Ω	1.78 k Ω	41.17 V	-2.0%
48 V	1.50 k Ω	1.54 k Ω	47.43 V	-1.2%

9.2.2.4 Inductor and Current Sense Resistor Selection

The inductor selection is based on consideration of both buck and boost modes of operation and the range of the supported slope compensation. As inductor and current sense resistor influencing each other both needs to be selected depending on each other. A good starting point is to set the current sense resistor to have an average current level of 60% of the overcurrent detection level. This considers an inductor ripple ΔI_L of 20% and a margin of 20% to the overcurrent detection level. The highest inductor current appears at the lowest input voltage.

$$I_{L\ Peak, \max, \text{est.}} = \frac{V_{OUT}}{V_{IN, \min}} \times I_{OUT} \times 1.4 = 15.6\ A \quad (12)$$

The sense resistor can be calculated with:

$$R_{CS} = \frac{50\ mV}{I_{L\ Peak, \max, \text{est.}}} = 3.2\ m\Omega \quad (13)$$

The inductor can be selected with have a mid level slope compensation. This can be calculated with:

$$L = \frac{R_{CS} \times 625}{f_{SW}} = 3.35\ \mu H \quad (14)$$

Additionally, the inductor selection can be based on the peak-to-peak current ripple ΔI_L for buck and boost mode, depending if better efficiency for buck or boost operation is important. The target inductance for buck mode with approximately 60% of the maximum inductor current at the maximum input voltage is:

$$L_{BUCK} = \frac{(V_{IN(\text{MAX})} - V_{OUT}) \times V_{OUT}}{0.6 \times I_{OUT(\text{MAX})} \times F_{SW} \times V_{IN(\text{MAX})}} = 6.48\ \mu H \quad (15)$$

The target inductance for boost mode with approximately 30% of the maximum inductor current at the maximum input voltage is:

$$L_{BOOST} = \frac{V_{IN(\text{MIN})}^2 \times (V_{OUT} - V_{IN(\text{MIN})})}{0.3 \times I_{OUT(\text{MAX})} \times F_{SW} \times V_{OUT}^2} = 2.48\ \mu H \quad (16)$$

For this application, an inductor with 3.3 μH was selected.

The peak inductor current occurs at in this configuration occurs at minimum input voltage and with an efficiency of 95% is given by:

$$I_{L\ Peak\ Boost} = \frac{V_{OUT} \times I_{OUT}}{\eta \times V_{IN, \min}} + \frac{V_{IN, \min} \times (V_{OUT} - V_{IN, \min})}{2 \times L \times f_{SW} \times V_{OUT}} = 12.9\ A \quad (17)$$

For the current sense Resistor a margin of 20% is considered to have enough headroom for the dynamic responses, e.g. load step regulation. To ensure the maximum output current can be delivered the minimum level of the peak current limit threshold is used:

$$R_{CS} = \frac{39\ mV}{I_{L\ Peak\ Boost}} = 3.0\ m\Omega \quad (18)$$

The standard value of $R_{CS} = 2.5\ m\Omega$ with 2 times 5 $m\Omega$ is selected. With the 2 resistors in parallel it also reduces the parasitic inductance. The maximum power dissipation in R_{CS} happens at $V_{IN(\text{MAX})}$:

$$P_{R_{CS}(\text{Max})} = \left(\frac{59\ mV}{R_{CS}} \right)^2 \times R_{CS} \times \left(1 - \frac{V_{OUT}}{V_{IN(\text{MAX})}} \right) = 0.81\ W \quad (19)$$

9.2.2.5 Output Capacitor

In boost mode, the output capacitor conducts high ripple current. The output capacitor RMS ripple current is given by:

$$I_{\text{COUT(RMS)}} = I_{\text{OUT}} \times \sqrt{\frac{V_{\text{OUT}}}{V_{\text{IN}}} - 1} \quad (20)$$

where the minimum V_{IN} corresponds to the maximum capacitor current.

In this example, the maximum output ripple RMS current is $I_{\text{COUT(RMS)}} = 5.5$ A. A 3-mΩ output capacitor ESR causes an output ripple voltage of 33.3 mV as given by:

$$\Delta V_{\text{RIPPLE(ESR)}} = \frac{I_{\text{OUT}} \times V_{\text{OUT}}}{V_{\text{IN(MIN)}}} \times \text{ESR} \quad (21)$$

A 80-μF output capacitor causes a capacitive ripple voltage of 151 mV as given by:

$$\Delta V_{\text{RIPPLE(COUT)}} = \frac{I_{\text{OUT}} \times \left(1 - \frac{V_{\text{IN(MIN)}}}{V_{\text{OUT}}}\right)}{C_{\text{OUT}} \times f_{\text{SW}}} \quad (22)$$

Typically, a combination of ceramic and bulk capacitors is needed to provide low ESR and high ripple current capacity. [Section 9.2](#) shows a good starting point for C_{OUT} for typical applications.

9.2.2.6 Input Capacitor

In buck mode, the input capacitor supplies high ripple current. The RMS current in the input capacitor is given by:

$$I_{\text{CIN(RMS)}} = I_{\text{OUT}} \times \sqrt{D \times (1 - D)} \quad (23)$$

The maximum RMS current occurs at $D = 0.5$, which gives $I_{\text{CIN(RMS)}} = I_{\text{OUT}} / 2 = 2.5$ A. A combination of ceramic and bulk capacitors must be used to provide a short path for high di/dt current and to reduce the output voltage ripple. [Figure 9-1](#) is a good starting point for C_{IN} for typical applications.

9.2.2.7 Slope Compensation

For stable current loop operation and to avoid subharmonic oscillations, the slope resistor must be selected based on [Equation 24](#):

$$\text{SlopeComp} = \frac{R_{\text{CS}}}{L \times f_{\text{SW}}} \times 625 = 0.79 \quad (24)$$

The next higher value has to be selected which is 0.825 and then be set via R_{CFG1} or the I2C interface. This slope compensation results in “dead-beat” operation, in which the current loop disturbances die out in one switching cycle. Theoretically, a current mode loop is stable with half the “dead-beat” slope (considered already in the calculated slope resistor value in [Equation 24](#)). A smaller slope capacitor results in larger slope signal, which is better for noise immunity in the transition region (V_{IN} is approximately equal to V_{OUT}). A larger slope signal, however, restricts the achievable input voltage range for a given output voltage, switching frequency, and inductor. For this design, a slope compensation factor of 0.875 (see Configuration Pin CFG2) is selected for better transition region behavior while still providing the required V_{IN} range. This selection of slope capacitor, inductor, switching frequency, and inductor satisfies the COMP range limitation.

9.2.2.8 UVLO Divider

The UVLO resistor divider must be designed for turn-on below 8.7 V. Selecting $R_{UVLO,top} = 75\text{ k}\Omega$ gives a UVLO hysteresis of 0.375 V based on Equation 25. The lower UVLO resistor is selected using:

$$V_{(VIN,IT+,UVLO)} = V_{IT+(UVLO)} \times \left(1 + \frac{R_{UVLO,top}}{R_{UVLO,bot}}\right) + R_{UVLO,top} \times I_{(UVLO,hyst)} \quad (25)$$

A standard value of 12.4 k Ω is selected for $R_{UVLO,bot}$.

When programming the UVLO threshold for lower input voltage operation, it is important to choose MOSFETs with gate (Miller) plateau voltage lower than the minimum V_{IN} .

9.2.2.9 Soft-Start Capacitor

The soft-start time is programmed using the soft-start capacitor. The relationship between C_{SS} and the soft-start time is given by:

$$C_{SS} = \frac{I_{SS} \times t_{SS}}{V_{Ref}} = 18\text{ nF} \quad (26)$$

$C_{SS} = 18\text{ nF}$ gives a soft-start time of 1.8 ms.

9.2.2.10 MOSFETs QH1 and QL1

The input side MOSFETs QH1 (Q1) and QL1 (Q2) need to withstand the maximum input voltage of 48 V. In addition, they must withstand the transient spikes at SW1 during switching. Therefore, QH1 and QL1 must be rated for 58 V or higher. The gate plateau voltages of the MOSFETs must be smaller than the minimum input voltage of the converter, otherwise, the MOSFETs may not fully enhance during start-up or overload conditions.

The power loss in QH1 in boost mode is approximated by:

$$P_{COND(QH1)} = \left(I_{OUT} \times \frac{V_{OUT}}{V_{IN}}\right)^2 \times R_{DS,On(QH1)} \quad (27)$$

The power loss in QH1 in buck mode consists of both conduction and switching loss components given by Equation 28 and Equation 29, respectively:

$$P_{COND(QH1)} = \left(I_{OUT} \times \frac{V_{OUT}}{V_{IN}}\right)^2 \times R_{DS,On(QH1)} \quad (28)$$

$$P_{SW(QH1)} = \frac{1}{2} \times V_{IN} \times I_{OUT} \times (t_r + t_f) \times f_{SW} \quad (29)$$

The rise (t_r) and the fall (t_f) times are based on the MOSFET data sheet information or measured in the lab. Typically, a MOSFET with smaller $R_{DS,On}$ (smaller conduction loss) has longer rise and fall times (larger switching loss).

The power loss in QL1 in the buck mode of operation is shown in Equation 30:

$$P_{COND(QL1)} = \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \times I_{OUT}^2 \times R_{DS,On(QL1)} \quad (30)$$

9.2.2.11 MOSFETs QH2 and QL2

The output side MOSFETs QH2 (Q4) and QL2 (Q3) see the output voltage of 48 V and additional transient spikes at SW2 during switching. Therefore, QH2 and QL2 must be rated for 58 V or more. The gate plateau voltages of the MOSFETs must be smaller than the minimum input voltage of the converter, otherwise, the MOSFETs may not fully enhance during start-up or overload conditions.

The power loss in QH2 in buck mode of operation is approximated by:

$$P_{COND(QH2)} = I_{OUT}^2 \times R_{DS, On(QH2)} \quad (31)$$

The power loss in QL2 in the boost mode of operation consists of both conduction and switching loss components given by:

$$P_{COND(QL2)} = \left(1 - \frac{V_{IN}}{V_{OUT}}\right) \times \left(I_{OUT} \times \frac{V_{OUT}}{V_{IN}}\right)^2 \times R_{DS, On(QL2)} \quad (32)$$

and, respectively:

$$P_{SW(QL2)} = \frac{1}{2} \times V_{OUT} \times \left(I_{OUT} \times \frac{V_{OUT}}{V_{IN}}\right) \times (t_r + t_f) \times f_{SW} \quad (33)$$

The rise (t_r) and the fall (t_f) times can be based on the MOSFET data sheet information or measured in the lab. Typically, a MOSFET with smaller $R_{DS, On}$ (lower conduction loss) has longer rise and fall times (larger switching loss).

The power loss in QH2 in the boost mode of operation is shown below:

$$P_{COND(QH2)} = \frac{V_{IN}}{V_{OUT}} \times \left(I_{OUT} \times \frac{V_{OUT}}{V_{IN}}\right)^2 \times R_{DS, On(QH2)} \quad (34)$$

9.2.2.12 Loop Compensation

This section presents the control loop compensation design procedure for the LM51772 buck-boost controller. The LM51772 operates mainly in buck or boost modes, separated by a transition region, and therefore, the control loop design is done for both buck and boost operating modes. Then, a final selection of compensation is made based on the mode that is more restrictive from a loop stability point of view. Typically, for a converter designed to go deep into both buck and boost operating regions, the boost compensation design is more restrictive due to the presence of a right half plane zero (RHPZ) in boost mode.

The boost power stage output pole location is given by:

$$f_{p1(boost)} = \frac{1}{2\pi} \left(\frac{2}{R_{OUT} \times C_{OUT}} \right) = 995 \text{ Hz} \quad (35)$$

where

- $R_{OUT} = 5.0 \, \Omega$ corresponds to the maximum load of 5.0 A.

The boost power stage ESR zero location is given by:

$$f_{z1} = \frac{1}{2\pi} \left(\frac{1}{R_{ESR} \times C_{OUT}} \right) = 73.7 \text{ kHz} \quad (36)$$

The boost power stage RHP zero location is given by:

$$f_{RHP} = \frac{1}{2\pi} \left(\frac{R_{OUT} \times (1 - D_{MAX})^2}{L_1} \right) = 39.1 \text{ kHz} \quad (37)$$

where

- D_{MAX} is the maximum duty cycle at the minimum V_{IN} .

The buck power stage output pole location is given by:

$$f_{p1(buck)} = \frac{1}{2\pi} \left(\frac{1}{R_{OUT} \times C_{OUT}} \right) = 497 \text{ Hz} \quad (38)$$

The buck power stage ESR zero location is the same as the boost power stage ESR zero.

It is clear from Equation 39 that RHP zero is the main factor limiting the achievable bandwidth. For a robust design, the crossover frequency must be less than 1/3 of the RHP zero frequency. Given the position of the RHP zero, a reasonable target bandwidth in boost operation is around 8 kHz:

$$f_{bw} = 8 \text{ kHz} \quad (39)$$

For some power stages, the boost RHP zero may not be as restrictive, which happens when the boost maximum duty cycle (D_{MAX}) is small, or when a really small inductor is used. In those cases, compare the limits posed by the RHP zero ($f_{RHP} / 3$) with 1/20 of the switching frequency and use the smaller of the two values as the achievable bandwidth.

The compensation zero can be placed at 1.5 times the boost output pole frequency. Keep in mind that this locates the zero at three times the buck output pole frequency, which results in approximately 30 degrees of phase loss before crossover of the buck loop and 15 degrees of phase loss at intermediate frequencies for the boost loop:

$$f_{ZC} = 1.5 \text{ kHz} \quad (40)$$

The compensation gain resistor, R_{c1} , is calculated with:

$$R_{c1} = \frac{2\pi \times f_{bw}}{g_{mEA}} \times \frac{R_{FB1} + R_{FB2}}{R_{FB2}} \times \frac{A_{CS} \times R_{CS} \times C_{OUT}}{1 - D_{MAX}} \times \frac{1}{\sqrt{1 + \left(\frac{f_{bw}}{f_{RHP}} \right)^2}} = 7.4 \text{ k}\Omega \quad (41)$$

where

- D_{MAX} is the maximum duty cycle at the minimum V_{IN} in boost mode.
- A_{CS} is the current sense amplifier gain.

The compensation capacitor, C_{c1} , is then calculated from:

$$C_{c1} = \frac{1}{2\pi \times f_{ZC} \times R_{c1}} = 14.5 \text{ nF} \quad (42)$$

The standard values of compensation components are selected to be $R_{c1} = 7.32 \text{ k}\Omega$ and $C_{c1} = 15 \text{ nF}$.

A high frequency pole (f_{pc2}) is placed using a capacitor (C_{c2}) in parallel with R_{c1} and C_{c1} . Set the frequency of this pole at seven to ten times of f_{bw} to provide attenuation of switching ripple and noise on COMP while avoiding excessive phase loss at the crossover frequency. For a target $f_{pc2} = 98 \text{ kHz}$, C_{c2} is calculated using Equation 43:

$$C_{c2} = \frac{1}{2\pi \times f_{pc2} \times R_{c1}} = 263 \text{ pF} \quad (43)$$

Select a standard value of 270 pF for C_{c2} . These values provide a good starting point for the compensation design. Each design must be tuned in the lab to achieve the desired balance between stability margin across the operating range and transient response time.

9.2.2.13 External Component Selection

Table 9-3. Components Example for Typical Application

Reference	Description	Part Number	Comment
R _{COMP}	7.32 kΩ

9.3 Power Supply Recommendations

The LM51772 is designed to operate over a wide input voltage range. The characteristics of the input supply must be compatible with the *Absolute Maximum Ratings* and *Recommended Operating Conditions*. In addition, the input supply must be capable of delivering the required input current to the fully loaded regulator. Use [Equation 44](#) to estimate the average input current.

$$I_I = \frac{P_O}{V_I \eta} \quad (44)$$

where

- η the efficiency.

If the device is connected to an input supply through long wires or PCB traces with a large impedance, take special care to achieve stable performance. The parasitic inductance and resistance of the input cables can have an adverse effect on converter operation. The parasitic inductance in combination with the low-ESR ceramic input capacitors form an under-damped resonant circuit. This circuit can cause overvoltage transients at VIN each time the input supply is cycled ON and OFF. The parasitic resistance causes the input voltage to dip during a load transient. One way to solve such issues is to reduce the distance from the input supply to the regulator and use an aluminum or tantalum input capacitor in parallel with the ceramics. The moderate ESR of the electrolytic capacitors helps to damp the input resonant circuit and reduce any voltage overshoots. An EMI input filter is often used in front of the controller power stage. Unless carefully designed, it can lead to instability as well as some of the previously mentioned affects.

9.4 Layout

9.4.1 Layout Guidelines

9.4.1.1 Power Stage Layout

Input capacitors, output capacitors, and MOSFETs are the constituent components of the power stage of the buck-boost regulator and are typically placed on the top side of the PCB. The benefits of convective heat transfer are maximized when leveraging any system-level airflow. In a two-sided PCB layout, small-signal components are typically placed on the bottom side. Insert at least one inner plane, connected to ground, to shield, and isolate the small-signal traces from noisy power traces.

The DC/DC regulator has several high-current loops. Minimize the area of these loops to suppress generated switching noise and optimize switching performance.

- The most important loop areas to minimize are the path from the input capacitors through the buck high-side and low-side MOSFETs, and back to the ground connection of the input capacitor and the path from the output capacitors through the boost high-side and low-side MOSFETs, and back to the ground connection of the output capacitor. Connect the negative terminal of the capacitor close to the source of the low-side MOSFETs (at ground). Similarly, connect the positive terminal of the capacitor or capacitors close to the drain of the high-side MOSFETs of both loops.
- In addition to these recommendation, follow any layout considerations of the MOSFETs as recommended by the MOSFET manufacturer, including pad geometry and solder paste stencil design.

9.4.1.2 Gate Driver Layout

The LM51772 high-side and low-side gate drivers incorporate short propagation delays, frequency depended dead-time control, and low-impedance output stages capable of delivering large peak currents with very fast rise and fall times to facilitate rapid turn-on and turn-off transitions of the external power MOSFETs. Very high di/dt can cause unacceptable ringing if the trace lengths are not well controlled. Minimization of stray or parasitic gate loop inductance is key to optimizing gate drive switching performance, whether it be series gate inductance that resonates with MOSFET gate capacitance or common source inductance (common to gate and power loops) that provides a negative feedback component opposing the gate drive command, and thereby increasing MOSFET switching times.

Connections from the gate driver outputs, HO1 and HO2, to the respective gates of the high-side MOSFETs must be as short as possible to reduce series parasitic inductance. Route HO1 and HO2 and SW1 and SW2 gate traces as a differential pair from the device pin to the high-side MOSFET, taking advantage of flux cancellation by reducing the loop area.

Connections from gate driver outputs, LO1 and LO2, to the respective gates of the low-side MOSFETs must be as short as possible to reduce series parasitic inductance. Route LO1 and LO2, and PGND traces as a differential pair from the device pin to the low-side MOSFET, taking advantage of flux cancellation by reducing the loop area.

Minimize the current loop path from the VCC, HB1, and HB2 pins through their respective capacitors as these provide the high instantaneous current.

9.4.1.3 Controller Layout

With the provision to locate the controller as close as possible to the power MOSFETs to minimize gate driver trace runs, the components related to the analog and feedback signals as well as current sensing are considered in the following:

- Separate power and signal traces, and use a ground plane to provide noise shielding.
- Place all sensitive analog traces and components related to COMP, FB, SLOPE, SS/ATRK, and RT away from high-voltage switching nodes such as the following to avoid mutual coupling:
 - SW1
 - SW2
 - HO1
 - HO2
 - LO1
 - LO2
 - HB1
 - HB2
- Use an internal layer or layers as ground plane or planes. Pay particular attention to shielding the feedback (FB) trace from power traces and components.
- Route the CSA and CSB and ISNSP and ISNSN traces as differential pairs to minimize noise pickup and use Kelvin connections to the applicable shunt resistor.
- Locate the upper and lower feedback resistors close to the FB pins, keeping the FB traces as short as possible. Route the trace from the upper feedback resistor or resistors to the output voltage sense point.
- Use a common ground node for power ground and a different one for analog ground to minimize the effects of ground noise. Connect these ground nodes at any place close to one of the ground pins of the IC.
- The HTSSOP package offers a means of removing heat from the semiconductor die through the exposed thermal pad at the base of the package. While the exposed pad of the package is not directly connected to any leads of the package, it is thermally connected to the substrate (ground) of the device. This connection allows a significant improvement in heat sinking, and it becomes imperative that the PCB is designed with thermal lands, thermal vias, and a ground plane to complete the heat removal subsystem.

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

DATE	REVISION	NOTES
October 2023	*	Advance Information Release

11 Device and Documentation Support

TI offers an extensive line of development tools. Tools and software to evaluate the performance of the device, generate code, and develop solutions are listed below.

11.1 Documentation Support

11.1.1 Related Documentation

11.2 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on [ti.com](https://www.ti.com). Click on *Subscribe to updates* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

11.3 Support Resources

TI E2E™ [support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

11.4 Trademarks

TI E2E™ is a trademark of Texas Instruments.

WEBENCH® is a registered trademark of Texas Instruments.

All trademarks are the property of their respective owners.

11.5 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

11.6 Glossary

[TI Glossary](#)

This glossary lists and explains terms, acronyms, and definitions.

Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

PLASTIC QUAD FLATPACK - NO LEAD

NOTES:

1. All linear dimensions are in millimeters. Any dimensions in parenthesis are for reference only. Dimensioning and tolerancing per ASME Y14.5M.
2. This drawing is subject to change without notice.
3. The package thermal pad must be soldered to the printed circuit board for thermal and mechanical performance.

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
XLM51772RHAR	ACTIVE	VQFN	RHA	40	4000	TBD	Call TI	Call TI	-40 to 125		Samples

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSELETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

Important Information and Disclaimer:The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
